<td>31-Mar-20</td>
<td>Applying Palliative Care Principles to Communicate With Children About COVID-19</td>
<td>Journal of Pain and Symptom Management</td>
<td>Original Article</td>
<td>Palliative care teams encourage families to ground their communication on COVID-19 with children on key values: (1) honesty and trust: an honest answer for children with underlying health conditions would be to acknowledge; (2) self-compassion: adults should admit emotions, such as fear, anxiety, and sadness, and then model healthy habits to live through these real feelings; (3) safety: as children sense a lack of human control, teaching children tangible ways to try to be safer can be empowering; (4) sensitivity: intuitive and conscious awareness of the child’s level of curiosity, maturity, developmental stage, and current emotion are essential to protect the child from too much or too little information; (5) connection: with school closures and skilled nursing lockdowns, deliberate and creative forms of connection offer children the security of human connection; (6) preparedness: consider discussing preparedness in a way that models caring for the community vs. hoarding; (7) community building: avoiding nationalistic language and xenophobia phrasing protects children from creating a sense of other vs. us; (8) recognition of death as a part of the life cycle: families may consider to share family beliefs about the meaning of a good life; (9) legacy: discussing with children the ways that history has impacted the community may be a way to help the child consider this current pandemic in a larger context.</td>
<td>This article summarizes communication training and skillsets to help families consider caring ways to communicate with their children and grandchildren about COVID-19.</td>
<td>Weaver MS, Wiener L. Applying Palliative Care Principles to Communicate With Children About COVID-19. J Pain Symptom Manage. 2020;60(1): e8-e11. doi: 10.1016/j.jpainsymman.2020.03.020</td>

<td>Pregnancy, emergency cesarean section, neonate, amniotic fluid, placenta, cord blood, South Korea</td>
<td>31-Mar-20</td>
<td>Emergency cesarean section on severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) confirmed patient</td>
<td>Korean Journal of Anesthesiology</td>
<td>Case Report</td>
<td>This case report describes the first case of a SARS-CoV-2 positive pregnant woman, who delivered via cesarean section at 37+6 weeks gestation in the Republic of Korea. Obstructed labor with incomplete rotation of the fetal head provided indication for cesarean section. The neonate was born 6 minutes after incision and was transferred immediately to a private room in the NICU. SARS-CoV-2 RT-PCR results using placenta, amniotic fluid, and cord blood samples were negative. Neonatal nasopharyngeal swabs were also negative on two consecutive SARS-CoV-2 RT-PCR tests. A negative pressure operating room, skillful medical team, personal protective equipment, and powered air-purifying respirator were employed for this safe delivery.</td>
<td>A neonate born to a mother with confirmed COVID-19 tested negative on two consecutive SARS-CoV-2 RT-PCR tests. Placenta, amniotic fluid, and cord blood samples were also negative.</td>

<td>Nutritional management, ICU stay, malnutrition, poly-morbidity, Europe</td>
<td>31-Mar-20</td>
<td>ESPEN Expert Statements and Practical Guidance for Nutritional Management of Individuals With SARS-CoV-2 Infection</td>
<td>Clinical Nutrition</td>
<td>Editorial</td>
<td>Poor outcomes and higher mortality due to COVID-19 are reported in immunocompromised patients, namely older adults and poly-morbid individuals, as well as generally malnourished people. ICU stay, poly-morbidity and older age are all commonly associated with high risk for malnutrition, representing a relevant risk factor for higher morbidity and mortality in chronic and acute disease. At the same time, prolonged ICU stays, required for stabilization of clinically severe COVID-19, may directly worsen or cause malnutrition, leading to severe loss of skeletal muscle mass and function. Prevention, diagnosis and treatment of malnutrition should therefore be routinely included in the management of COVID-19 patients. In this document, the European Society for Clinical Nutrition and ESPEN provides practical recommendations for the nutritional management of COVID-19 patients in the ICU, who face higher risk of malnutrition during prolonged ICU stays.</td>
<td>ESPEN provides practical recommendations for the nutritional management of COVID-19 patients with SARS-CoV-2 infection [published online, 2020 Mar 31]. Clin Nutr. 2020. doi:10.1016/j.clnu.2020.03.022</td>

<td>Pediatric Inflammatory Bowel Disease, immunomodulatory drugs, biologic treatment, China, South Korea</td>
<td>31-Mar-20</td>
<td>COVID-19 and Paediatric Inflammatory Bowel Diseases: Global Experience and Provisional Guidance (March 2020) from the Paediatric IBD Porto group of ESPGHAN.</td>
<td>Journal of Pediatric Gastroenterology and Nutrition</td>
<td>Societal Paper</td>
<td>Concerns have been raised over the risk of COVID-19 to children with inflammatory bowel disease (IBD). This paper gathers global experience, from a circulating electronic reporting system of children with IBD infected with SARS-CoV-2, along with surveys completed by major PIBD centers in China and South Korea. Eight PIBD children had COVID-19 globally, all with mild infection and without need for hospitalization despite treatment with immunomodulators and/or biologics. No cases have been reported in China and South Korea, but biologic treatment has been delayed in 79 children, of whom 17 (22%) had exacerbation of their IBD. Authors provide provisional guidance for managing PIBD in the era of COVID-19: standard IBD treatments including biologics should continue at present, especially in children who have severe IBD course and milder SARS-CoV-2 infection.</td>
<td>Authors describe the clinical course of COVID-19 in children with underlying IBD, receiving treatment with immunomodulators and/or biologics, and summarizes guidance points for management of PIBD in the era of COVID-19.</td>
<td>Turner D, Huang Y, Martín-de-Carpi J, et al. <td>Children, childhood obesity, weight gain, school closings, social distancing</td>
<td>30-Mar-20</td>
<td>COVID-19 Related School Closings and Risk of Weight Gain Among Children.</td>
<td>Obesity</td>
<td>Perspective</td>
<td>Authors anticipate that social distancing measures and school closures due to the COVID-19 pandemic will likely double out-of-school time this year for many children in the U.S. As a result, risk factors for weight gain conventionally associated with summer recess, such as consumption of calorie-dense foods and lack of physical activity, may be exacerbated. The risk of overnutrition and weight gain is linked to food insecurity, which may be worsened in the context of missed school meals, contributing to disparities in health and educational attainment.</td>
<td>School closures in many areas of the U.S., due to the COVID-19 crisis, may exacerbate the epidemic of childhood obesity and increase disparities in obesity risk.</td>
<td>Rundle AG, Park Y, Herbstman JB, Kinsey EW, Wang YC. COVID-19 Related School Closings and Risk of Weight Gain Among Children [published online, 2020 Mar 30]. Obesity (Silver Spring). 2020. doi:10.1002/oby.22813</td>

<td>30-Mar-20</td>
<td>International Perspectives Concerning Donor Milk Banking During the SARS-CoV-2 (COVID-19) Pandemic</td>
<td>Journal of Human Lactation</td>
<td>Insights into Practice and Policy</td>
<td>Based on personal communications with colleagues in China, Italy, and the author's own donor milk bank in the United States, the author has attempted to document the pandemic's current effect on donor milk banking as well as donor milk supply and demand. There is heightened anxiety in donors who must interact with the healthcare system to have their blood drawn for screening, or when they drop off their milk at the milk bank. The author's organization is engaged in educating mothers that there is no evidence of coronavirus transmission through human milk and that previous coronaviruses have been destroyed by pasteurization. Other milk banking organizations have issued statements upholding the importance of donor milk and recommending the addition of questions about risk of COVID-19 exposure to donor screening protocols, as well as deferral of donors who report symptoms or test positive for SARS-CoV-2.</td>
<td>This article discusses the effects of the COVID-19 crisis on donor milk banking and details programmatic changes and emergency preparedness strategies implemented at a non-profit U.S. milk bank to ensure sustained supply of donor milk, transport of &quot;safe&quot; milk from donors to milk banks under quarantine, and support for breastfeeding mothers.</td>
<td>Marinelli KA. International Perspectives Concerning Donor Milk Banking During the SARS-CoV-2 (COVID-19) Pandemic [publis H+7 hed online ahead of print, 2020 Mar 30]. J Hum Lact. 2020. doi:10.1177/0890334420917661</td>

<td>30-Mar-20</td>
<td>Maternal and Neonatal Outcomes of Pregnant Women With COVID-19 Pneumonia: A Case-Control Study</td>
<td>Clinical Infectious Diseases</td>
<td>Original Research</td>
<td>This case-control study compares clinical characteristics, maternal and neonatal outcomes of pregnant women with and without COVID-19 pneumonia at a tertiary hospital in Wuhan, China. From January 24 to February 29, 2020, 34 pregnant women with confirmed or suspected COVID-19 were admitted to labor in the third trimester. Compared to controls, COVID-19 pneumonia patients had lower counts of white blood cells, neutrophils, C-reactive protein, and ALT on admission. Five mothers with confirmed or suspected COVID-19 pneumonia had preterm delivery, which was significantly higher than the control group. None experienced respiratory failure during hospital stay. COVID-19 infection was not found in the newborns, and none developed severe neonatal complications.</td>
<td>This is one of the first case control studies to assess the association between COVID-19 pneumonia and maternal neonatal outcomes.</td>
<td>Li N, Han L, Peng M, et al. Maternal and neonatal outcomes of pregnant women with COVID-19 pneumonia: a case-control study [published online, 2020 Mar 30]. Clin Infect Dis. 2020;ciaa352. doi:10.1093/cid/ciaa352</td>

| Pregnancy, postpartum fever, neonates, China | 28-Mar-20 | Clinical analysis of pregnant women with 2019 novel coronavirus pneumonia | Journal of Medical Virology | Research Article | Five cases of pregnant women with confirmed COVID-19 were identified among patients admitted to the Maternal and Child Hospital of Hubei Province between January 20 and February 10, 2020. Ages of patients ranged from 25 to 31 years old, and gestational ages ranged from 38 to 41 weeks. None of the patients had antepartum fever, but all developed a low-grade fever (37.5°C-38.5°C) within 24 hours after delivery. All patients had normal liver and renal function; two patients had elevated plasma levels of the myocardial enzyme. Unusual chest imaging manifestations, namely ground-glass opacity, were frequently observed in bilateral (3/5) or unilateral lobe (2/5) by CT scan. There were no complications observed during labor or in newborns. All neonates tested negative for SARS-CoV-2 infection by quantitative RT-PCR. | children were absent or rarely noted in early reports, and the associated morbidity in COVID-19 was deemed as mostly mild. Children and infants may play a pivotal role in community-based transmission of SARS-CoV-2. | Chen S, Liao E, Shao Y. Clinical analysis of pregnant women with 2019 novel coronavirus pneumonia [published online, 2020 Mar 28]. J Med Virol. 2020. doi:10.1002/jmv.25789 |

<p>| Children, infants, symptoms, case definitions, vertical transmission | 27-Mar-20 | COVID-19 in the pediatric population | Dermatologic Therapy | Letter to the Editor | The authors describe the current knowledge of how the COVID-19 pandemic impacts pediatric populations and what previous cases and studies indicate. Three neonatal cases with COVID-19 were reported and highlight the possibility of COVID-19 vertical transmission to infant during delivery or breastfeeding. A study evaluated 9 hospitalized infants infected with COVID-19 who did not show clinical progression requiring intensive care. Another study showed a high frequency (83.3%) of COVID-19 RNA detection and prolonged virus RNA shedding in feces of pediatric patients for more than 1 month. This highlights a likelihood of poor performance of current case definitions of COVID-19, especially in infants. One study demonstrated that chest imaging alterations in infected children with COVID-19 might occur earlier than clinical symptoms and that allow early identification of the large underdiagnosed suspected pneumonia cases. In conclusion, most of the pediatric patients with COVID-19 have mild symptoms, without fever or pneumonia, and will recover within 1-2 weeks after disease onset. | The authors describe previous cases and studies to explain that most of the pediatric patients with COVID-19 have mild symptoms, without fever or pneumonia, and will recover within 1-2 weeks after disease onset. The authors critique that current case definitions of COVID-19 are poor, particularly for infants. | Abdelmaksoud A, Kroumpouzos G, Jafferany, M, et al. COVID-19 in the pediatric population. Dermatologic Therapy. 2020;33:e13339. doi:10.1111/dth.13339 |</p>

<td>27-Mar-20</td>
<td>Epidemiology and Transmission of COVID-19 in Shenzhen China: Analysis of 391 cases and 1,286 of their close contacts</td>
<td>medRxiv</td>
<td>Original Research</td>
<td>The Shenzhen CDC identified 391 SARS-CoV-2 cases from January 14 to February 12, 2020 and 1,286 close contacts. Cases were older than the general population (mean age: 45 years) and balanced between males (187) and females (204). 91% had mild or moderate clinical severity at initial assessment. Three have died, 225 have recovered (median time to recovery: 21 days). Cases were isolated on average 4.6 days after developing symptoms; contact tracing reduced this by 1.9 days. Household contacts and those travelling with a case were at higher risk of infection (ORs 6 and 7) than other close contacts. The household secondary attack rate was 15%, and children were as likely to be infected as adults. The observed reproductive number was 0.4, with a mean serial interval of 6.3 days.</td>
<td>Surveillance data from Shenzhen, China show that children are at similar risk of SARS-CoV-2 infection as the general population, though less likely to have severe symptoms.</td>
<td>Bi C, Wu Y, Mei S, et al. Epidemiology and Transmission of COVID-19 in Shenzhen China: Analysis of 391 cases and 1,286 of their close contacts.</td>

<td>Antibodies in Infants Born to Mothers With COVID-19 Pneumonia</td>
<td>JAMA</td>
<td>Research Letter</td>
<td>New serological diagnostic criteria (released by the Chinese National Health Commission on Mar 4) were applied to a cohort of 6 pregnant women with confirmed COVID-19, admitted to Zhongnan Hospital, Wuhan from February 16 to March 6, 2020. All six mothers had mild clinical manifestations and cesarean deliveries in their third trimester in negative pressure isolation rooms. Infants were isolated from their mothers immediately after delivery. While neonatal throat swabs and blood samples tested negative for viral nucleic acid by RT-PCR, virus-specific antibodies were detected in the blood serum of all six infants. IgG concentrations (passively transferred across the placenta beginning in the second trimester) were elevated in six infants (not usually passively transferred), and IgM concentrations were detected in two infants. Abnormal weight and pathology of placenta in mothers with SARS have been noted (Ng et al, 2006), but placental damage among women in this study is unknown. IgM could have been produced by the fetus if the virus crossed the placenta. Inflammatory cytokine IL-6 was also significantly increased in all neonatal sera samples.</td>
<td>This research builds upon an earlier cohort study of nine pregnant women from the same hospital (Chen et al, Feb 2020). New data on serological characteristics of mothers and newborns. The presence of anti-SARS-CoV-2 IgM in 2 infants suggests possible transplacental transmission. Study is limited by lack of cord blood, amniotic fluid, and breast milk data.</td>
<td>Zeng H, Xu C, Fan J, et al. Antibodies in Infants Born to Mothers With COVID-19 Pneumonia [published online, 2020 Mar 26]. JAMA. 2020;e204861. doi:10.1001/jama.2020.4861</td>

<tr>
<td>Serological testing, breastfeeding, vertical transmission, IgM / IgG concentrations, cytokine levels, China</td>
<td>26-Mar-20</td>
<td>Possible Vertical Transmission of SARS-CoV-2 From an Infected Mother to Her Newborn</td>
<td>JAMA</td>
<td>Research Letter</td>
<td>This case report describes the birth of an infant with elevated anti-SARS-CoV-2 IgM antibodies and cytokine levels, despite no physical contact with a mother with laboratory-confirmed COVID-19. The mother developed COVID-19 symptoms and was admitted to Renmin Hospital, Wuhan on January 28, 2020, where she received antiviral, antibiotic, corticosteroid, and oxygen therapies. RT-PCR tests of the patient’s vaginal secretions were negative. An infant girl was delivered on February 22, 2020 by cesarean section in a negative pressure isolation room; she was immediately quarantined in the NICU. At two hours of age, the neonate had elevated IgG and IgM levels (usually appear 3 to 7 days after infection) and abnormal cytokine test results. Mother’s breastmilk tested negative by RT-PCR elevated IgM levels.</td>
<td>Elevated IgM levels in a neonate born to a mother with confirmed COVID-19 increase suspicion of transmission in utero. However, the infant’s repeatedly negative RT-PCR test results are difficult to explain. Study limitations include lack of amniotic fluid.</td>
<td>Dong L, Tian J, He S, et al. Possible Vertical Transmission of SARS-CoV-2 From an Infected Mother to Her Newborn [published online, 2020 Mar 26]. JAMA. 2020;e204621. doi:10.1001/jama.2020.4621</td>

<td>Children, MERS, SARS, routine immunization, cross-reactivity, MMR</td>
<td>25-Mar-20</td>
<td>Routine Childhood Immunization May Protect Against COVID-19</td>
<td>Medical Hypotheses</td>
<td>Letter to Editor</td>
<td>Different age groups are susceptible to infection, however SARS-CoV, MERS-CoV and SARS-CoV-2 seem to less commonly infect children and to cause milder symptoms and are associated with much lower case-fatality rates and most of them recover quickly from the infection. This mysterious lower rate of fatality and symptomatic illness could be advocated to the active viral immunization (e.g. varicella, Hepatitis B, MMR, Poliomyelitis, and rotavirus) of children globally, from birth till six years. Immunizations may build immunity against SARS-CoV-2 by protecting lung cells from invasion. MMR is already been used to induce bystander immunity against other virus strains.</td>
<td>Cross-reactivity from common childhood immunizations (e.g. MMR) may explain lower case fatality rates and susceptibility of children to SARS-CoV-2 infection. Future clinical trials must assess the prophylactic and/or therapeutic efficacy of other vaccinations for emerging COVID-19.</td>
<td>Salman S, Salem ML. Routine childhood immunization may protect against COVID-19 [published online, 2020 Mar 25]. Med Hypotheses. 2020;140:109689. doi:10.1016/j.mehy.2020.109689</td>

<td>A pregnant woman with COVID-19 in Central America</td>
<td>Travel Medicine and Infectious Disease</td>
<td>Case Report</td>
<td>On March 9, 2020, a 41-year-old female, who was 31 weeks pregnant, with gestational hypertension and preeclampsia, presented to the Hospital Escuela of Tegucigalpa, Honduras, with intermittent fever, dry cough, headache and myalgias for three days. She had a history of travelling in Madrid, Spain, where she had lived for the past six months. Given the patient’s travel history and fever, a nasopharyngeal aspirate sample was collected and tested following WHO guidelines for real-time RT-PCR, and results were positive. On admission, she presented bilateral conjunctival hyperemia. An obstetric ultrasound revealed a fetus with a dysplastic and multicystic right kidney with no other alterations. After ten days of hospitalization, she was stable, remaining under observation until delivery. On March 19, 2020, at 32 weeks of gestation, she delivered a male newborn by spontaneous vaginal delivery. The neonate’s nasopharyngeal and blood samples tested by SARS-CoV-2 rRT-PCR were negative. Although asymptomatic, the mother’s nasopharyngeal sample remained positive at the time of birth.</td>
<td>This case report describes a pregnant woman with confirmed COVID-19 in Honduras, who gave birth to a male newborn by vaginal delivery. The neonate’s nasopharyngeal and blood samples tested negative for SARS-CoV-2 following birth.</td>

<td>COVID-19 in Children: The Link in the Transmission Chain</td>
<td>The Lancet Infectious Diseases</td>
<td>Comment</td>
<td>Evidence has shown that children are susceptible to SARS-CoV-2 infection but frequently do not have notable disease, raising the possibility that children could be facilitators of viral transmission. In terms of treatment, it is unclear which children should be targeted for antiviral and immunomodulatory therapy, particularly in view of the high proportion of asymptomatic infected contacts. Together, these results could suggest that children have specific mechanisms regulating the interaction between the immune system and respiratory machinery, which could be contributing to milder disease.</td>
<td>This article reviews the clinical report from Qiu et al. on pediatric patients with confirmed COVID-19, and discusses questions that remain to be answered, especially related to immune mechanisms and treatment.</td>
<td>Kelvin AA, Halperin S. COVID-19 in children: the link in the transmission chain [published online, 2020 Mar 25]. Lancet Infect Dis. 2020. doi:10.1016/S1473-3099(20)30236-X</td>

<td>Children, observational cohort, epidemiology, aerosolized interferon alpha, China</td>
<td>25-Mar-20</td>
<td>Clinical and epidemiological features of 36 children with coronavirus disease 2019 (COVID-19) in Zhejiang, China: an observational cohort study</td>
<td>The Lancet Infectious Diseases</td>
<td>Article</td>
<td>From January 17 to March 1, 2020, 36 children with confirmed SARS-CoV-2 were identified at three hospitals in Zhejiang, China. The route of transmission was by close contact with family members or history of exposure to the epidemic area. The majority presented with mild pneumonia or were asymptomatic. Decreased lymphocytes, elevated body temperature, and high levels of procalcitonin, D-dimer, and creatine kinase MB were associated with greater severity of disease. All children received interferon alpha by aerosolization twice a day, 14 (39%) received lopinavir–ritonavir syrup twice a day, and six (17%) needed oxygen inhalation. Mean time in hospital was 14 (SD: 3) days.</td>
<td>The large proportion of asymptomatic children indicates the difficulty in identifying pediatric patients without clear epidemiological information, leading to a potentially dangerous situations in community acquired infections.</td>
<td>Davies N, Klepac P, Lui Y et al. Age dependent effects in the transmission and control of COVID-19 epidemics [available online, 24 Mar 2020]. medRxiv. doi:10.1101/2020.03.24.20043018</td>

<td>Children, epidemiology, coronaviruses, cross-protection, Norway</td>
<td>24-Mar-20</td>
<td>COVID-19 – A Mild Disease in Children</td>
<td>Tidsskriftet Den Norske Nor Laegeforening</td>
<td>Opinion</td>
<td>In Norway, 65 children in the 0–19 age group were reported to have been infected with COVID-19 as of March 20, 2020. This number is approximately 3.3% of all COVID-19 cases in Norway. The fact that very few children have tested positive in this outbreak is consistent with other coronavirus outbreaks in recent history, such as SARS and MERS. The reasons why children are relatively unaffected by COVID-19 remain unclear. Do children have absolute protection against infection or only against the risk of developing the disease after being infected? Do children develop cross-protection from having encountered other types of coronavirus? This article explores potential reasons and concludes that children have minimal risk of developing COVID-19 as well as experiencing a fatal outcome.</td>
<td>Reported cases of COVID-19 in the 0–19 age group in Norway have been low; this article considers why children are relatively spared by COVID-19.</td>

<tr>
<td>Children, age-specificity, clinical severity, susceptibility, mathematical model</td>
<td>24-Mar-20</td>
<td>Age-dependent effects in the transmission and control of COVID-19 epidemics</td>
<td>medRxiv</td>
<td>Original Article</td>
<td>The COVID-19 pandemic has shown a markedly low proportion of cases among children. Age disparities in observed cases could be explained by assortative mixing patterns and reactive school closures which decrease mixing between children, or by children exhibiting lower susceptibility to infection, or by children having a lower propensity to show clinical symptoms. Authors formally tested these hypotheses by fitting an age-structured mathematical model to epidemic data from six countries, finding strong age dependence in the probability of developing clinical symptoms, rising from around 20% in patients under 10 years old to over 70% in older adults. Authors found that interventions aimed at halting transmission in children may have minimal effects on preventing cases depending on the relative transmissibility of subclinical infections. Estimated age-specific clinical fraction has implications for the expected global burden of clinical cases because of demographic differences across settings. In younger populations, the expected clinical attack rate would be lower, although it is likely that comorbidities in low-income countries will affect disease severity. Without effective control measures, regions with older populations may see disproportionally more clinical cases, particularly in the later stages of the pandemic.</td>
<td>Based on age-structured mathematical models, this study determined that the plausibility of age-specific severity of COVID-19 disease is higher than age-specific susceptibility to COVID-19 infection.</td>
<td>Davies N, Klepac P, Lui Y et al. Age dependent effects in the transmission and control of COVID-19 epidemics [available online, 24 Mar 2020]. medRxiv. doi:10.1101/2020.03.24.20043018</td>

<td>Children, clinical characteristics, multicenter study, China</td>
<td>24-Mar-20</td>
<td>Clinical Characteristics of Children with Coronavirus Disease 2019 in Hubei, China</td>
<td>Current Medical Science</td>
<td>Article</td>
<td>A cross-sectional multicenter study was carried out in 10 hospitals across Hubei province. A total of 25 confirmed pediatric cases of COVID-19 were collected. The boy to girl ratio was 1.27:1 and the median age was 3 years. The most common symptoms at onset of illness were fever (13 [52%]), and dry cough (11 [44%]). Chest CT images showed essential normal in 8 cases (33.3%), unilateral involvement of lungs in 5 cases (20.8%), and bilateral involvement in 11 cases (45.8%). Clinical diagnoses included upper respiratory tract infection (n=8), mild pneumonia (n=15), and critical cases (n=2). Two critical cases (8%) were given invasive mechanical ventilation, corticosteroids, and immunoglobulin. The symptoms in 24 (96%) of 25 patients were alleviated and one patient had been discharged. It was concluded that children were susceptible to COVID-19 like adults, while the clinical presentations and outcomes were more favorable in children. However, children less than 3 years old accounted for the majority of critical cases.</td>
<td>This article reinforces that clinical presentation and outcomes are more favorable in children than adults. Younger children (&lt;3 years old) accounted for the majority of cases and critical cases, which warrants further attention.</td>

<td>Pregnancy, patho, physiology, vertical transmission, breastfeeding, skin-to-skin contact</td>
<td>23-Mar-20</td>
<td>Coronavirus Disease 2019 (COVID-19) Pandemic and Pregnancy</td>
<td>American Journal of Obstetrics &amp; Gynecology</td>
<td>Special Report</td>
<td>To date, the outcomes of 55 pregnant women and 46 neonates infected with COVID-19 have been reported in the literature, with no concrete evidence of vertical transmission. Physiological and mechanical changes in pregnancy increase susceptibility to infections in general, particularly when the cardiorespiratory system is affected. Pregnancy bias towards Th2 system dominance, which protects the fetus, leaves the mother vulnerable to viral infections, which are more effectively contained by the Th1 system. Although data doesn't suggest risk of vertical transmission, delayed clamping of the umbilical cord and skin-to-skin contact should be avoided following delivery. There is no definitive evidence of vertical transmission, but skin-to-skin contact should be avoided following delivery. Breastfeeding is not contraindicated, but a face mask should be worn.</td>
<td>There is no definitive evidence of vertical transmission, but skin-to-skin contact should be avoided following delivery. Breastfeeding is not contraindicated, but a face mask should be worn.</td>
<td>Dashraath P, Jing Lin Jeslyn W, Mei Xian Karen L, et al. Coronavirus Disease 2019 (COVID-19) Pandemic and Pregnancy [published online, 2020 Mar 23]. Am J Obstet Gynecol. 2020. doi:10.1016/j.ajog.2020.03.021</td>
</tr>
</tbody>
</table>
delivery. Breastfeeding is not contraindicated based on retrospective analysis of COVID-19 in pregnancy that showed absence of detectable viral loads of SARS-CoV-2 in breastmilk. Regardless, a face mask should be worn due to the close proximity between mother and child to reduce the risk of droplet transmission. The presence of coronavirus antibodies in breastmilk depends on the gestation at which maternal infection occurred and if there was any preceding use of high-dose corticosteroids which could suppress maternal antibody responses.

<td>Children, clinical severity, symptomatic case fatality risk, China</td>
<td>19-Mar-20</td>
<td>Estimating clinical severity of COVID-19 from the transmission dynamics in Wuhan, China</td>
<td>Nature Medicine</td>
<td>Letter</td>
<td>As of February 29, 2020, there were 79,394 confirmed cases and 2,838 deaths due to COVID-19 in mainland China. Of these, 48,557 cases and 2,169 deaths occurred in the epicenter, Wuhan. A key public health priority during the emergence of a novel pathogen is estimating clinical severity, which requires properly adjusting for the case ascertainment rate and the delay between symptoms onset and death. Using public and published information, the overall symptomatic case fatality risk (sCFR, the probability of dying after developing symptoms) of COVID-19 in Wuhan is estimated at 1.4% (0.9-2.1%). The sCFR for ages 0-9 is 0.3% (0.1-0.7%), and for ages 10-19 is 0.5% (0.3-0.8%). Compared to those aged 30-59 years, those aged &lt;30 and &gt;59 years were 0.6 (0.3-1.1) and 5.1 (4.2-6.1) times more likely to die after developing symptoms.</td>
<td>Children with COVID-19 in Wuhan, China experience lower symptomatic case fatality risk, compared to adults 30 years old and above.</td>

<td>Children, clinical characteristics, China</td>
<td>16-Mar-20</td>
<td>Clinical Characteristics of 34 Children with Coronavirus Disease-2019 in the West of China: a Multiple-center Case Series</td>
<td>medRxiv</td>
<td>Case Series</td>
<td>This retrospective, observational study was performed at 4 hospitals in western China. Thirty-four pediatric patients (aged 1 to 144 months, median: 33 months, IQR: 10-94.25) with COVID-19 were included from January 1 to February 25, 2020. The final follow-up visit was completed by February 28, 2020. Among 34 pediatric patients, 14 males (41.18%) were included. The median incubation period was 10.50 (7.75 - 25.25) days. Infections of other respiratory pathogens were reported in 16 patients (47.1%). The most common initial symptoms were fever (76.5%), cough (58.8%), and expectoration (20.7%). Vomiting (11.8%) and diarrhea (11.8%) were also reported in a considerable portion of cases. A remarkable increase was detected in serum amyloid A for 17 patients (85.0%) and high-sensitivity C-reactive protein for 17 patients (58.6%), while a decrease of prealbumin was noticed in 25 patients (78.1%). In addition, levels of lactate dehydrogenase were increased significantly in 28 patients (82.4%), as well as α-hydroxybutyrate dehydrogenase in 25 patients (73.5%). Patchy lesions in lobules were detected by chest computed tomographic scans in 28 patients (82.4%). The typical feature of ground-glass opacity for adults was rare in pediatric patients (2.9%). A late-onset pattern of lesions in lobules were also noticed. Stratified analysis of the clinical features was not performed due to relatively limited samples.</td>
<td>suspected or confirmed SARS-CoV-2 infection in China between January 16 - February 8, 2020. Although clinical manifestations of children’s COVID-19 cases were generally less severe than those of adult patients, young children, particularly infants, were vulnerable to infection. The distribution of children's COVID-19 cases varied with time and space, with most cases concentrated in Hubei province and surrounding areas.</td>

<tr>
<td>Pediatrics, epidemiology, China</td>
<td>16-Mar-20</td>
<td>Epidemiological Characteristics of 2143 Pediatric Patients With 2019 Coronavirus Disease in China</td>
<td>Pediatrics</td>
<td>Original Article</td>
<td>This study retrospectively analyzed the epidemiological characteristics and transmission patterns of 2143 pediatric patients with COVID-19, reported to the Chinese Center for Disease Control and Prevention from January 16 to February 8, 2020. Approximately 34% were laboratory-confirmed cases, and 66% were suspected cases. Children at all ages were susceptible to COVID-19, but no significant gender difference was found. Over 90% of patients were asymptomatic, mild, or moderate cases. It is speculated that the maturity and function, i.e. binding ability, of the ACE2 receptor in children may be lower than that in adults. Infants were at the highest risk of severe disease (10.6%), compared with older children (4.1% for those aged 11 to 15 years; 3.0% in those 16 years and older).</td>
<td>This is the first retrospective study on the epidemiological characteristics of children with COVID-19 in China. There were more severe and critical cases in the suspected than confirmed group; whether suspected cases were caused by 2019-nCoV or other pathogens remains to be determined.</td>
<td>Dong Y, Mo X, Hu Y, Qi X, Jiang F, Jiang Z, et al. Epidemiological Characteristics of 2143 Pediatric Patients With 2019 Coronavirus Disease in China. Pediatrics. 2020. doi:10.1542/peds.2020-0702</td>

<td>Pediatrics, clinical characteristics, virologic testing, viral shedding, community-based transmission</td>
<td>16-Mar-20</td>
<td>COVID-19 in Children: Initial Characterization of the Pediatric Disease</td>
<td>Pediatrics</td>
<td>Commentary</td>
<td>This commentary reviews the findings of Dong et al. from the same issue of Pediatrics. There are subpopulations of children with an increased risk for more significant illness, related to factors of younger age, underlying pulmonary pathology, and immunocompromising conditions. Testing for other viruses in the study by Dong et al. was not standardized, and not all COVID-19 cases were virologically confirmed. Children may play a major role in community-based viral transmission, based on evidence that children may have more upper, rather than lower, respiratory tract involvement, as well as prolonged viral shedding in stool and nasal secretions.</td>
<td>This article reviews current understanding of epidemiological, virological, and clinical characteristics of disease in children. Authors note that virological testing in the Dong et al. study was not standardized.</td>

<td>Children, fecal viral shedding, convalescent phase, China</td>
<td>13-Mar-20</td>
<td>Prolonged presence of SARS-CoV-2 in feces of pediatric patients during the convalescent phase.</td>
<td>medRxiv</td>
<td>Case Report</td>
<td>From January 17 to March 6, 2020, three pediatric cases of COVID-19 were reported in Qingdao, Shandong Province, China. Real-time fluorescence RT-PCR was performed to detect SARS-CoV-2 RNA in throat swabs and fecal specimens. All three pediatric cases were household contacts of adults whose symptoms developed earlier. There has been no evidence showing the virus was transmitted from the children to others. Severity of disease of these children was mild to moderate, and fever was the most consistent and predominant symptom at onset of illness. All children showed increased lymphocytes with normal white blood cell counts on admission. One child had elevated serum levels of procalcitonin and C-reactive protein. Radiological changes were not typical for COVID-19. All children showed good response to supportive treatment. Clearance of SARS-CoV-2 in respiratory tract samples occurred within two weeks after abatement of fever, whereas persistent presence of viral RNA was found in stools of all children. In one child, fecal samples turned negative 8 days after throat swabs turned negative, while fecal samples of another child lagged behind for 20 days. At the time of writing, one child still had positive results for RT-PCR analysis in stools after negative conversion of viral RNA in respiratory samples (over 19 days behind).</td>
<td>Prolonged shedding of SARS-CoV-2 viral RNA in stools of three infected children in this report indicates the potential for viral transmission through fecal excretion.</td>

</table>
### Summary & Key Points

Presented with unilateral pulmonary lesions (30%), 10 with bilateral pulmonary lesions (50%), and 4 cases showed no abnormality on chest CT (20%). Consolidation with surrounding halo sign was observed in 10 patients (50%), ground-glass opacities were observed in 12 patients (60%), fine mesh shadow was observed in 4 patients (20%), and tiny nodules were observed in 3 patients (15%).

### Specific Observations

Sputum samples from a woman with confirmed COVID-19 tested positive following delivery, while amniotic fluid, umbilical cord blood, placenta, and breast milk samples tested negative.

<td>Archives of Disease in Childhood -</td>
<td>Letter</td>
<td>This article outlines recommendations regarding newborns: Infants with highly suspected or confirmed COVID-19 should be referred to the designated neonatal ward. All medical staff involved should wear protective equipment. The neonatal department should be strictly stratified into transitional, quarantine, living and work areas. Infants with suspected infections should be isolated in a single room, while confirmed patients should be moved into separate rooms. After admission, avoiding breastfeeding from COVID-19 mother until recovery should be adequately performed. Recommendations outlined in this letter discourage breastfeeding until after recovery.</td>

<td>The Lancet Child &amp; Adolescent Health</td>
<td>Original Research</td>
<td>Authors prospectively followed 31 confirmed cases (&lt;18 years) with SARS-CoV-2 infection in Shenzhen Third People’s Hospital between January 16, 2020, and February 19, 2020. All 31 cases were confirmed as having SARS-CoV-2 in upper respiratory tract specimens by real-time RT-PCR. None of the cases had Hunan seafood market exposure. 29 (93.5%) children belong to family clusters. 12 (38.7%) children had no symptoms. Fever was observed in 14 (45.2%) children, with a duration of 1–9 days (median: 2 [IQR 1–3]). 13 (41.9%) cases had cough. Lymphocytes above the normal range were seen in 17 children. 12 (38.7%) children exhibited elevated lactate dehydrogenase levels. Increased erythrocyte sedimentation rate was seen in 10 (32.3%) patients. Chest CT images were normal in 20 (64.5%) cases. 8 (25.8%) patients showed unilateral pneumonia, and 1 patient showed progress for bilateral pneumonia (Table 4). 3 (9.7%) patients had bilateral pneumonia. 23 (74.2%) children had been discharged, at the time of this study.</td>
<td>This prospective cohort of 31 confirmed cases of SARS-CoV-2 infection in children &lt;18 years found a milder clinical course of disease, compared to adults.</td>

<td>Coronavirus disease (COVID-19) and neonate: What neonatologist need</td>
<td>Journal of Medical Virology</td>
<td>Review</td>
<td>Three neonates and more than 230 children with COVID-19 are reported. Children presented with mild conditions. There is currently no evidence that SARS-CoV-2 can be transmitted trans-placentally from mother to the newborn. The treatment strategy for children with COVID-19 is based on adult experience. Thus far, no deaths have been reported in the pediatric age group. This review describes the current understanding of COVID-19 infection in newborns and children, as well as treatment.</td>
