Preface

There are over 100 million forcibly displaced persons globally, including refugees, asylum seekers, and internally displaced persons as of May 2022.¹ These people fled their homes for a variety of reasons, including persecution, conflict, violence, human rights violations, discriminatory environments, and economic hardship. Included amongst these displaced persons are those from Venezuela, who have left their country to escape some of these difficulties for better horizons. Currently, there are over 7.1 million Venezuelan refugees, asylum seekers and migrants worldwide, most residing in Latin America and the Caribbean countries.² This displacement of Venezuelans has become one of the largest external displacement crises globally.³ Colombia has been the largest host of Venezuelans nationals, offering approximately 2.5 million migrants and refugees permanent residence in Colombia, as well as offering services to all displaced persons in Colombian territory in a transitory situation.^{2.4}

Despite the unprecedented dimensions of the crisis in the region, the response has also been unprecedented and, although there remains much to cover, HIV has been present in the humanitarian response agenda, not only from the viewpoint of people living with HIV (PLHIV), but also with growing commitment to reduce risk of HIV for migrants. The difficult conditions of migratory processes may increase susceptibility to infections and clinical complications. Familial separation, interruption of support networks and livelihoods, lack of food security and barriers to healthcare or education increase migrants' vulnerability to HIV; conversely, a migrant soliciting asylum has a higher likelihood of preventing HIV if their host country has options which facilitate social and laboral integration, such as access to essential medical services.

Public health responses to HIV imply addressing inequalities in such a way that vulnerable populations such as migrants are guaranteed human rights, social protection, and socio-economic and cultural integration, which are well-known determinants of health. The provision of culturally appropriate HIV services depends upon a myriad of information and data, including a population's HIV prevalence, as well as vulnerability and risk factors. Measuring HIV prevalence amongst displaced persons who reside outside of camps is a major challenge that has rarely been undertaken successfully.

The authors of this important report, entitled "Behavioral survey of HIV, syphilis, and health status among Venezuelans living in Colombia" have adapted respondent-driven sampling (RDS), a method employed for populations without sampling frames, for use among Venezuelan refugees, asylum seekers and migrants living in Bogotá, Soacha, Barranquilla, and Soledad, Colombia. The RDS methodology allowed for estimation

of population estimates and overcomes limitations associated with other convenience sampling approaches and HIV estimates generated through data from testing programs. RDS is particularly well-suited to measure HIV and other disease prevalences amongst displaced populations in non-camp-like settings. The primary objective of the study was to estimate HIV prevalence among adult Venezuelans who have arrived and have resided in Colombia since 2015. Together with other important data such as overall livelihood, health, and displacement experiences, as well as experiences of discrimination and violence, these findings will inform local health and humanitarian services for Venezuelans living in Colombia. This study also provided an opportunity to validate the importance of the principle of "greater involvement of the affected populations" (GIPA),⁵ given the involvement of the community since the initial design of the study. A lesson learned is the advantage of involving community-based organizations across all phases of the investigation, building on their expertise and relationships to inform the methodology and understand results, as pillars of evidence-based advocacy.

We will not repeat the results of the study in this preface. Rather, we wish to highlight some of the key aspects that we believe this study has undertaken successfully, in the hope that the results will improve the quality of lives and reduce morbidity and mortality amongst Venezuelans living in Colombia. The study points to clear interventions that can reduce HIV vulnerability and risk amongst Venezuelans residing in Colombia, including the improvement of food security, reduction of discrimination and violence, and programs to address intimate partner violence. Context matters, and the study noted disparities across migration status and geographic residence. Contrary to stereotypes, behavioral risks for HIV were relatively low amongst migrants and refugees, but history of HIV testing and access to HIV services were also low. Low engagement across the HIV care continuum shows a need to increase uptake of HIV testing and support long-term and consistent engagement in care for Venezuelans in Colombia. Because location of HIV acquisition was mixed, i.e., some people living with HIV came to Colombia knowing they were living with HIV and others acquired HIV while living in Colombia, programmatic planning must take into consideration both the transnational continuity of care and local prevention and testing services. Finally, Venezuelans with irregular migration status were significantly less likely to have suppressed viral loads, demonstrating a clear link between legal status and HIV outcomes of clinical and public health significance. Collectively, this study provides valuable data to inform local and regional human rights-based HIV responses⁶ that include supporting enabling laws and policies, such as the Temporary Protection Status,⁷ alongside expanded HIV service provision.

Finally, we hope that other HIV studies with different displaced populations around the world will be conducted with the same rigor and innovation as this study to improve the lives of the over 100 million persons who are currently displaced globally; only then will we have quality results to improve response strategies and leave nobody behind.

Sincerely,

Luisa Cabal

Director Regional Office for Latin America and the Caribbean UNAIDS

Biobehavioral Survey of HIV, Syphilis, and Health Status Among Venezuelans Living in Colombia

Executive Summary

Executive Summary

INTRODUCTION

The economic crisis and political instability in the Bolivarian Republic of Venezuela has led to mass migration and displacement in the Americas, displacing over 7.1 million Venezuelans as of September 2022.² The humanitarian emergency has been associated with deteriorating healthcare infrastructure and worsening health outcomes among Venezuelans living in the country, as well as among those displaced to neighboring countries.⁸ Colombia currently receives the largest number of displaced Venezuelans in the region. As of September 2022, approximately 2.5 million were living in multiple departments across Colombia (Figure 1).² Few population-based estimates are available to assess the experiences and health of Venezuelans living in Colombia.

Figure 1 Population distribution of Venezuelan migrants and refugees¹ in Colombia as of 2021

(Source: Department of Migration)

Access to health services, as well as employment, education, health care, and banking, in Colombia is largely dependent on one's immigration status. People with regular migration status, defined as entering the country through regular pathways that are consistent with the laws and regulations governing exit from, entry, and stay in the destination country, or who have gone through the process of obtaining documentation after entry, are able to gain formal employment and thus enroll in the contributory system or receive services under the national subsidized system for uninsured people.^{9,10} However, as of March 2021 (prior to the beginning of this study), 56% of the 1.7 million Venezuelans residing in Colombia at that time had irregular migration status,¹¹ i.e., lacked legal status in Colombia. These individuals are not able to access formal employment, and are thus unable to access the contributory insurance system, and are ineligible for the subsidized system.^{9,10} This also includes access to HIV treatment for people living with HIV, some of whom may have migrated to Colombia due to ART (anti retroviral treatment) and other HIV care related supply shortages in Venezuela.¹²

¹ Note; The term refugees and migrants is used throughout this report in recognition of the complexity of their displacement and for consistency with terminology used by regional agencies involved in coordinating the humanitarian response. Refer to reference 2 for further details.

Donations of HIV medications have made treatment available regardless of migration status in Cúcuta, a border city in Colombia with many Venezuelans living there or crossing the border temporarily to access treatment, and more recently in Bogotá.^{13,14} In other areas of the country, treatment options for migrants and refugees with irregular migration status are limited, though several organizations provide HIV testing and other health and support services for Venezuelan migrants and refugees. Most recently, the Temporary Protection Permit for Venezuelans (*Estatuto Temporal de Protección para Migrantes Venezolanos* or ETP), which came into effect in 2021, was expected to provide legal protection and, therefore, access to health and other social services for an estimated 800,000 Venezuelans with irregular migration status in Colombia.⁷ Population-based estimates of health indicators and HIV are absent but needed to inform public health programming and humanitarian response. Estimates of the burden of HIV and other health indicators are needed to inform treatment distribution plans for future drug donations,¹⁵ HIV programming, and public health policies.

The biobehavioral survey, known as *Bienestar de Venezolanos quienes son Inmigrantes y Refugiados* (*Proyecto BIENVENIR*) ("Wellbeing of Venezuelans who are Immigrants and Refugees"), was conducted among adult Venezuelan migrants and refugees in four urban cities of Colombia. The primary objective of this study was to estimate HIV prevalence among adult Venezuelans in two sites (which cover two neighboring cities per site) who have arrived and reside in Colombia since 2015. Given lack of information on the overall livelihood, health, displacement experiences, and experiences of discrimination and violence, additional information was collected in these domains noting their relationship to HIV as social and structural determinants of health as well as to inform local health and humanitarian services.

METHODS

This study was designed and implemented using a community-academic-policy partnership model, which provided comprehensive expertise across all aspects of the study. Collaborators included Red Somos, a community-based organization that provided HIV support and legal services for Venezuelan migrants and refugees in Colombia, the Colombian Ministry of Health and Social Protection, and academic research institution, Johns Hopkins University Bloomberg School of Public Health.

Venezuelan adults who migrated since 2015 and resided in the Bogotá, Soacha, Barranquilla, or Soledad metropolitan areas were sampled using respondent-driven sampling (RDS), a non-probability chain referral sampling method.¹⁶ The target sample size for RDS enrollment was 6,200 participants, which was powered to detect HIV prevalence in each site with a 0.005 margin of error. Eligibility was restricted to one member per household as well as to people with no immediate plan to leave Colombia (i.e., *caminantes*, being those passing through Colombia to another country, and *pendulares*, being Venezuelans residing in Venezuela and traveling to Colombia daily or regularly, were not eligible for participation).

Participants completed socio-behavioral surveys and rapid, dual HIV/syphilis screening tests. The SD BIOLINE HIV/Syphilis Duo has a reported sensitivity of 99.8% and specificity of 100% for anti-HIV antibody detection and a reported sensitivity of 90% and specificity of 99.9% for anti-*Treponema pallidum* antibody detection.¹⁷ Laboratory-based confirmatory testing via Western Blot, CD4 count, and viral load measures were conducted for participants with a reactive HIV test following national HIV testing guidelines.¹⁸ Participants with a rapid treponemal test were provided laboratory-based rapid plasma reagin (RPR) test and titer to confirm syphilis infection. Participants diagnosed with HIV or syphilis were provided post-test counseling with integrated medicolegal services to provide legal assistance for sustained access to treatment through the national health system and were linked to care. Study implementation was led by Red Somos. Data collection launched on July 28, 2021 in Bogotá, July 31, 2021 in Soacha, August 10, 2021 in Barranquilla, and August 18, 2021 in Soledad. Participants were enrolled through February 2022, with final follow-up of participants with HIV and/ or syphilis diagnosis completed by end of March 2022.

Data were regularly reviewed to minimize bias and missingness, as well as to verify that assumptions underlying RDS estimation were achieved. Descriptive statistics were used to describe sample characteristics and generate population-based (RDS-weighted) estimates using the Volz-Heckathorn estimator.¹⁶ Multivariable logistic regression models were used to identify correlates of HIV infection. Among participants

living with HIV infection (previously diagnosed or undiagnosed), we conducted further descriptive analysis to estimate the proportion previously diagnosed, engaged in HIV care, currently on ARV treatment, and virally suppressed to construct HIV care continuum estimates of Venezuelans living with HIV in Colombia. Penalized logistic regression models were used to identify correlates of viral suppression (HIV RNA <1,000 copies/mL) among people living with HIV. Population estimates that were not stratified by site, as well as multivariable regression models, incorporated complex survey design to account for clustering within site strata.

This section of Excutive Summary provides a brief summary of study results, while detailed tables and study results are presented in full in the following chapters.

RESULTS

In total, 6,506 people were recruited through RDS, 6,221 of whom were eligible and consented to participate and compose the analytic sample. Participants were evenly distributed across the four cities. Women represented 65% of the study population and were more likely to enroll than men (34%) and trans or nonbinary participants (1%). Higher enrollment of women than men was anecdotally explained by the restriction of enrollment to one family member per household and gender norms associated with expectations of work and participation in health services (and, by extension research) within a partnership. Overall, participants were a relatively young population with a median age of 32 years, (Interquartile range [IQR]: 26-41 years).

Demographics and displacement: Migration escalated in 2017 and peaked in 2018-2019, primarily motivated by food and job insecurity. Access to health care or to give birth was not a frequently reported primary motivation for migration (Figure 2). Almost two-thirds of migrants and refugees entered Colombia via informal border crossings; half traveled with some proportion of their family, and 40% traveled alone.

The impacts of the economic disaster in Venezuela were reflected by incomplete educational attainment (20% who completed primary or less), high levels of unemployment or informal work in Colombia, and low income. While food insecurity was a primary motivation for migration, over 90% of Venezuelan refugees and migrants met classifications of low and very low food security in Colombia at the time of the study. Seventy-one percent of migrants and refugees had an irregular migration status and these individuals frequently experienced more hardships, such as food insecurity, lower educational attainment, and lower employment while in Colombia when compared to those with a regular migration status.

CREDIT: ADOBE STOCK

Figure 2 Reported primary motivation for migration to Colombia, stratified by site

General health: Approximately half of migrants and refugees had a BMI (body mass index) consistent with overweight or obesity (defined as >=25) based on self-reported height and weight. The prevalence of underweight body mass index (<= 18.5) was less than 10% overall, but slightly more common among people with irregular migration status. Among sexually active women, 52% reported currently using contraception and over 28% reported pregnancy since coming to Colombia. Reproductive health and prenatal care were generally not different by migration status in terms of sexual activity, number of births, or contraceptive use; however, women with regular migration status also reported marginally more prenatal care visits during their most recent pregnancy in Colombia.

Over 25% of migrants and refugees suspected they had COVID-19 infection at some point based on symptoms and exposure. This was more commonly reported by those with regular migration status, who also more frequently accessed COVID-19 testing, compared to people with irregular migration status, despite no difference in result of the test across migration status. Forty-eight percent reported having at least one vaccination for COVID-19, which was more commonly reported by migrants and refugees with regular compared to irregular status (55% vs. 44%). For irregular migrants and refugees, their migration status was the most common barrier to vaccination, while conflicts with work and inability to register for the vaccine were more frequently cited barriers to vaccination among regular migrants and refugees. Despite health concerns and social and structural challenges, migrants and refugees generally reported high levels of health status, with over three quarters of the sample reporting "good, very good, or excellent" health with no difference by migration status.

Mental and behavioral health: More than 20% of migrants and refugees reported symptoms indicative of moderate or severe anxiety and/or depression and 21% reported symptoms consistent with hazardous or active alcohol use disorder. The prevalence of anxiety/depression was different across sites with higher levels in Barranquilla and Soledad than in Bogotá and Soacha (29% vs. 16%).

Sexual behaviors and HIV infection: Almost all refugees and migrants were sexually active (96%), with a median number of one sexual partner in the past 12 months and nearly a third who reported condom use at last sex. Key populations at risk for HIV represented 7% of migrants and refugees overall. This included those who reported lifetime history of paying for sex (1%), lifetime transactional sex (2%), and lifetime injecting drug use (2%) among all migrants and refugees, as well as lifetime same-sex sexual partnerships among men (12%). Almost half did not know their sexual partner's HIV status, which was more commonly reported by women, people residing in Barranquilla and Soledad, and people with irregular migration status, compared to their counterparts. Only half of migrants and refugees reported any lifetime HIV test, which was higher among

people residing in Bogotá and Soacha (56%) compared to Barranquilla and Soledad (47%). History of HIV testing was more commonly reported among women and likely attributed to testing during prenatal care. Use of both post-exposure prophylaxis (PEP) and pre-exposure prophylaxis (PrEP) were low.

Laboratory confirmed HIV prevalence among migrants and refugees was 0.9% (95%CI: 0.6-1.4) overall and ranged from 0.8% in Bogotá and Soacha (95%CI: 0.4-1.5) to 1.2% (95%CI: 0.7-2.0) in Barranquilla & Soledad (Table 1). Prevalence was marginally higher among men (1.6%; 95%CI: 0.9-2.6) than women (0.6%; 95%CI: 0.2-1.2), though with overlapping confidence intervals. Assuming stable HIV prevalence among migrants and refugees and a population size of 2,477,588 refugees and migrants in Colombia, based on September 2022 migration estimates that includes all migration statuses,² this would equate to 22,298 (95%CI: 14,865 - 34,686) migrants and refugees living with HIV in Colombia and requiring ongoing access to treatment.

Table 1 HIV prevalence estimates

Notes: n: denominator for subgroup; N: total study population; 95%CI: 95% Confidence Interval; *Significantly different from reference group or across categories at *p<0.05 or **p<0.10 in chi² tests; Ref: reference group not displayed; Key population defined as individuals who identify as transgender or nonbinary who have sex with men, are men who have sex with men, report lifetime transactional sex, or report lifetime injecting drug use.

Population HIV prevalence was not calculated for transgender and non-binary identified participants due to the small number (n=47); however, the burden of HIV was high among this group with 8.5% (4/47) identified with HIV infection. HIV prevalence was estimated at 6% among key populations, inclusive of migrants and refugees who reported lifetime transactional sex, injecting drug use, trangender people who have sex with men, and men who have sex with men. Notably, all key populations with HIV were men who have sex with men or transgender/non-binary people, though several also reported other HIV acquisition risk behaviors such as injecting drug use or transactional sex. There was no difference in HIV status by migration status nor year of migration.

In terms of HIV outcomes, the most significant drop in the HIV care continuum is observed with diagnosis, wherein only 48% of people living with HIV had been previously diagnosed (Figure 3). Lack of awareness of one's status then impacts all subsequent stages of the continuum. Sevent-nine percent of those ever diagnosed were currently on treatment and 92.6% of those on treatment were virally suppressed (HIV-1 RNA <1,000 copies/mL). Overall, however, this represents 35.2% of people living with HIV who were virally suppressed. Twenty-nine percent of people living with HIV had an undetectable viral load (HIV-1 RNA <50 copies/mL).

Penalized multivariable logistic regression modeling was used to identify correlates of viral suppression (HIV-1 RNA <1,000 copies/mL) among participants living with HIV (n=71; Table 2). In the multivariable model, having an irregular migration status compared to a regular status was associated with a 70% reduced odds of viral suppression (adjusted odds ratio [aOR]: 0.3; 95%CI: 0.1-0.9), while having a last HIV test in Colombia, compared to Venezuela, was associated with a 90% reduced odds of viral suppression (aOR: 0.1; 95%CI: 0.0-0.5). Likewise, those who were never tested for HIV had 80% reduced odds of viral suppression, compared to those last tested in Venezuela. Reporting behaviors or identity associated with a key population and use of humanitarian services in Colombia were associated with viral suppression at the bivariate level but were no longer associated in the multivariable models. Gender, time since migration, site, age, income, food security, and BMI were not associated with viral suppression in bivariate or multivariable models.

Table 2 Correlates of viral suppression

| | OR | 95%CI | p-value | aOR | 95%CI | p-value |
|--|------|-----------|---------|-----|-----------|---------|
| Irregular migration status (Ref: Regular) | 0.2 | (0.1-0.6) | 0.004 | 0.3 | 0.1-0.9) | 0.026 |
| Key Population (Ref: General population | 3.0 | (1.1-7.9) | 0.029 | | | |
| Country of last HIV tests (Ref: Venezu | ela) | | | | | |
| Colombia | 0.2 | (0.0-0.7) | 0.015 | 0.1 | (0.0-0.5) | 0.008 |
| Never tested | 0.2 | (0.1-0.5) | 0.003 | 0.2 | (0.1-0.8) | 0.018 |
| Used humanitarian services (Ref: No use) | 2.7 | (0.9-7.6) | 0.063 | | | |

Note: OR: odds ratio; aOR: adjusted odds ratio calculated via a penalized multivariable logistic regression model for small denominators; final models are fit based on goodness of fit statistics and tested for collinearity;

History of STI and current syphilis infection: Overall, 3% of migrants and refugees reported a lifetime diagnosis of STI, among whom 81% received treatment either in Colombia or Venezuela.

Laboratory-confirmed syphilis infection, determined by rapid treponemal test and laboratory-based RPR, among migrants and refugees was 5.0% (95%CI: 4.1-6.0) and was not different by site nor migration status. Syphilis was slightly higher among men (6.5%), relative to women (4.1%). Among the sample of transgender and non-binary identified participants, 14.9% (unweighted) were identified with syphilis infection. Syphilis prevalence was estimated at 15.2% among key populations overall and as high as 18.2% among men who have sex with men.

Discrimination and violence victimization: Utilizing the Everyday Discrimination scale,¹⁹ almost 50% of migrants and refugees reported experiencing at least one form of discrimination a few times per year or more frequently. Ninety-percent attributed these experiences to their migration status.

Overall, 12% of migrants and refugees experienced violence while living in Colombia, which most commonly included psychological abuse, followed by physical violence, sexual exploitation, and sexual violence. The prevalence estimates of violence were different across sites and genders, as were the individuals reported to perpetrate violence. Generally, women more commonly reported that intimate partners had perpetrated violence, while men more commonly reported perpetration by police, armed groups, and strangers. Employers were more commonly reported by those with regular migrant status to perpetrate all forms of violence, compared to those with irregular status.

Hardships and use of humanitarian services: The vast majority of migrants and refugees (95%) reported some form of material hardship while living in Colombia, which predominantly included financial hardship (50%), food insecurity (20%), and housing instability (16%). Despite these challenges, only 17% of migrants and refugees reported utilizing humanitarian services. Among those who utilized services, these services often included food assistance (60%), support for accessing national health services (33%), healthcare (28%), and legal assistance (18%). There was no difference in overall utilization of humanitarian services across sites, though the type and provider of services differed across locations.

Migrants and refugees with regular status were more likely to have reported the use of humanitarian services compared to those with irregular status, though still fewer than one in five reported utilizing such services. Compared to irregular migrants and refugees, regular migrants and refugees were more likely to have reported use of legal or registration assistance, as well as assistance with accessing national health services, as well as services provided by UNHCR, which collectively may explain their successful obtainment of regular migration status.

CONCLUSIONS AND RECOMMENDATIONS:

This study successfully enrolled over 6,200 migrants and refugees residing in two urban settings of Colombia within eight months. The successful implementation is attributed to the community trust in the organization implementing field research, support for legal process to ensure linkage and sustained access to care for people diagnosed with HIV or syphilis regardless of migration status, and the use of RDS-methodology that leverages social networks within populations that lack sampling frames. The RDS methodology provides an added benefit of producing theoretically unbiased estimates that approximate population estimates and overcome limitations associated with other convenience sampling approaches and HIV estimates generated through testing programs.

Age distribution and timing of arrival reported here generally reflect what is reported by migration agencies for Venezuelans living in Colombia.²⁰ Our findings, however, also highlight social and structural vulnerabilities, including low educational attainment, low levels of formal employment and, thus, material hardships including low income, food insecurity, and housing instability. These likely reflect the long-term impacts of the financial crisis in Venezuela, but also immediate challenges facing Venezuelans in Colombia. For example, food insecurity was the most common reason for migration from Venezuela, however, food insecurity was the second most common reported hardship in Colombia, after financial difficulties.

To our knowledge, there are no estimates of discrimination and violence reported for Venezuelan refugees or migrants nor for adults of all genders in Colombia. We found that 50% of Venezuelans experienced discrimination and 12% experienced some form of psychological, physical, or sexual violence while residing in Colombia, which may suggest the existence of social tensions between the host and migrant community as well as the stress of displacement within families and intimate relationships. Given social vulnerabilities of migrant populations' vulnerabilities, in general, our estimates may be lower than expected but may be explained by the country's reputation for welcoming Venezuelans. Our formative, qualitative research found evidence of more recent tensions associated with the COVID-19 pandemic and economic impacts, however, and may reflect a change in public sentiment towards Venezuelans, which may translate to increased discrimination and/or violence in the near future. Ten percent of women refugees and migrants reported experiences of violence while living in Colombia; though not directly comparable, this is similar to national estimates of life-time and past 12 month intimate partner violence reported for ever-partnered women in Venezuela (19% and 8%, respectively) and Colombia in 2018 (20% and 12%, respectively).²¹ It is possible that separation of partners and families during migration may result lower reports of intimate and intrafamilial violence. These forms of violence may also be under-reported due to stigma or misclassification of less severe forms of violence.

In terms of health indicators, self-reported health status among migrants and refugees was generally high and may reflect the hypothesis known as the 'healthy migrant effect', in which migrants are often healthier than host communities in a number of health indicators.²² Other studies have supported that hypothesis, though have also shown that health tends to decline with length of stay, typically as a result of low living and working conditions.²² Indeed, mental and behavioral health indicators for Venezuelan migrants and refugees in this study were remarkable. Mean mental health scores on the PHO-4 among migrants and refugees were considerably higher than previously reported for the Colombian population in 2014 (3.3 vs. 1.3),²³ with onefifth of migrants and refugees reporting symptoms of anxiety or depression. Uptake of COVID-19 testing and vaccination was low, particularly among irregular migrants and refugees. Notably, this difference by migration status may reflect COVID-19 vaccination eligibility that was interpreted to be restricted to Colombian citizens and migrants/refugees with regular status; public health messaging changed in October 2021 to clarify that vaccinations were available for migrants and refugees with an irregular status. Finally, 5% of migrants and refugees had laboratory-confirmed syphilis infection. These estimates are far higher than 0.7% estimated prevalence among Colombian adults in 2016,²⁴ though cases of syphilis have increased in the country and regionally since that time.²⁵ The high prevalence of syphilis raises concerns for risks associated with untreated syphilis, congenital syphilis among other risks for neonates, and onward transmission of infection.

The prevalence of HIV was also noteworthy. Population HIV estimates bordered 1% (overall population prevalence: 0.9%; 95%CI: 0.6-1.4) and were higher in Barranquilla and Soledad (1.2%) than in Bogotá and Soacha (0.8%). HIV prevalence was 5% among key populations. Population prevalence of HIV was higher than

reported for Venezuela (0.5%)²⁶ and observed in Colombia (0.5%).²⁷ Low engagement across the HIV care continuum, beginning with low HIV diagnosis and ultimately low levels of viral suppression, signals a need to increase uptake of HIV testing and support long-term and consistent engagement in care for improved individual health outcomes as well as to prevent onward transmission of infection. The estimates reported here for Venezuelan migrants and refugees are close to those long defined by UNAIDS and WHO as a generalized epidemic²⁸ and highlight the importance of improving access to and uptake of HIV prevention and care among Venezuelan migrants and refugees in Colombia. These findings highlight and support prior guidance that migrants and refugees are not key populations and services for migrants and refugees should not be provided through key populations programs but incorporated through programs for the host population and via humanitarian programming.²⁹ Given that HIV burden was highest among key populations, programs serving key populations should continue to be supported, if not enhanced, to provide services to key populations regardless of nationality or migration status.

This study also identified notable disparities across migration status and geographic residence. Health history and services use suggested lower availability or access in Barranquilla and Soledad. Financial hardship was the most commonly reported hardship across both sites but was more common in Barranquilla and Soledad, while food and housing insecurity were more commonly reported hardships in Bogotá and Soacha. Differences speak broadly to the higher cost of living associated with Bogotá but also lower availability of services available in Barranquilla and Soledad, compared to Bogotá and Soacha. The differences across sites may also reflect differences in migration status among Venezuelans living in the two sites.

Venezuelan refugees and migrants with irregular migration status faced a number of social, structural and health vulnerabilities, compared to those with a regular migration status. Irregular migration status was associated with lower educational attainment, employment, income, food security, BMI, and higher levels of depression and anxiety, which collectively may reflect legal access to employment and other basic services. Low levels of condom use, awareness of partner status, diagnosed HIV infection, and viral suppression among people with irregular migration status reflect lack of access to insurance coverage for health and HIV services that are tied to legal migration status. Prenatal care is available regardless of migration status, but we observed a lower number of prenatal visits among women with irregular status, which likely reflects other barriers that may be associated with education or discrimination. Inexplicably, people with irregular migration status are vices. Despite these differences, health, social, and structural indicators were poor among Venezuelan refugees and migrants, overall. These findings highlight a need for improved access to services in addition to support migrants and refugees to understanding rights and services, particularly for those with lower literacy and education. For those with irregular status, methods to facilitate registration for the Temporary Protection Permit would improve access to health and other social services for an estimated 800,000 Venezuelans in Colombia.⁷

Study findings suggest multiple opportunities for intervention. This report concludes with recommendations for public health programming and policy to support improved health and well-being of Venezuelans living in Colombia.

Background

Background

CONTEXT OF MIGRATION AND HEALTH OUTCOMES AMONG VENEZUELANS

The economic crisis and political instability in the Bolivarian Republic of Venezuela has led to mass migration within the Americas. Over 7 million Venezuelan migrants and refugees have been displaced globally, with almost 6 million remaining in the Latin American and Caribbean region, as of September 2022.² This represented the largest external human displacement experienced in the Americas and was the second largest globally as of 2021.^{3,4} Colombia currently receives the largest number of Venezuelans refugees and migrants in the region. As of September 2022, approximately 2.5 million were living in Colombia.^{2,4,20,30,31}

The humanitarian emergency has been associated with deteriorating healthcare infrastructure and worsening health outcomes among Venezuelans living in the country, as well as among those displaced to neighboring countries.⁸ Contexts of high human mobility, especially when it is mostly outside of formal migration or humanitarian channels, may (or may not) change infectious disease transmission dynamics both for the receiving communities and for the migrants themselves, depending upon numerous factors. The COVID-19 pandemic has exacerbated public health concerns and strained the capacity of receiving countries to meet the healthcare needs of Venezuelan migrants and refugees.^{32,33}

ACCESS TO HIV SERVICES IN VENEZUELA AND FOR MIGRANTS AND REFUGEES IN COLOMBIA

The HIV epidemiology and health status of Venezuelans living in neighboring host countries is largely unknown. Gaps in HIV diagnostics and treatment in Venezuela since 2015 have limited the availability of reliable estimates of HIV burden. In 2018, the Pan-American Health Organization (PAHO) estimated that 69,308 people living with HIV, 87% of whom were registered to receive antiretrovirals (ARVs), were not receiving them due to nationwide drug shortages.¹² A coordinated response led by PAHO has improved ART coverage,³⁴ although diagnosis, treatment and suppression remain suboptimal. UNAIDS estimates that 100,000 people were living with HIV in Venezuela in 2020, with 71% of people living with HIV (PLHIV) diagnosed, and 55% of those diagnosed receiving ART.²⁶ No data on virologic suppression rates are available.²⁶ Less than one-third (30%) of pregnant women living with HIV had received ARVs for prevention of maternal-to-child transmission.²⁶

Access to HIV treatment for displaced Venezuelans in receiving countries is variable and depends on national health programs and policies of the host country. Data from other studies show that migrant populations, regardless of the situation or motivation for migration, often face delays in care and have higher risk of AIDS-defining events than non-migrant populations.³⁵ Treatment interruptions, including partial or intermittent treatment can lead to virologic rebound and increase the risk of onward transmission and acquired resistance.⁸ Diagnostic delays or other delays in access to treatment can also lead to ongoing transmission. These concerns, coupled with an estimated 25,000 Venezuelans crossing the Colombian border per day at the exodus' peak,^{36,37} underscore the importance of implementing appropriate surveillance methods coupled with access to HIV diagnosis, treatment, and care for migrant populations.

Access to health services, as well as employment, education, health care, and banking, in Colombia is largely dependent on one's immigration status. People with regular migration status, defined as entering the country through regular pathways that are consistent with the laws and regulations governing exit from, entry and stay in the destination country, or who have gone through the process of obtaining documentation after entry, are able to gain formal employment and thus enroll in the contributory system or receive services under the subsidized system for uninsured people.^{9,10} Fifty-six percent of the 1.7 million Venezuelans in Colombia as of March 2021 (prior to the beginning of this study),^{4,11} however, had irregular migration status, i.e. lack legal status in Colombia. These individuals are not able to access formal employment, and thus unable to access the contributory system, nor are they eligible for the subsidized system.^{9,10} They can, however, access emergency services and prenatal care. HIV treatment for Venezuelans with irregular migration status is not available

through the national health system, though drug donations have made treatment available in Cúcuta, a border city in Colombia where many Venezuelans reside or cross the border temporarily to access treatment, and more recently in Bogotá.^{13,14} In other areas of the country, treatment options for migrants and refugees with irregular migration status are limited, though several organizations provide HIV testing, support services, and prevention for Venezuelan migrants and refugees. Population-based estimates of HIV are absent, but needed to inform treatment distribution plans for future drug donations¹⁵ and national health programming.

EPIDEMIOLOGIC TRENDS

UNAIDS estimates from Venezuela in 2020 suggest the population prevalence of HIV among adults aged 15-49 in Venezuela is 0.5% (95%CI: 0.4% - 0.6%) and similar by gender²⁶. Prevalence estimates for adults in Colombia are similar and estimated at 0.5% (95%CI: 0.4% -0.7%) in 2021, though different by gender (women: 0.2%, 95%CI: 0.2-0.2%; men: 0.9%, 95%CI: 0.7%-1.1%).²⁷ There is no population-based estimate for migrants and refugees living with HIV in Colombia, though anecdotal evidence from antenatal care (ANC) services and local providers suggested a range of 0.5% to 1.5% test positivity and as high as 24% for key populations. Notably, positivity rates from HIV testing and ANC services are known to be higher than general population estimates due to inclusion of people with greater opportunities acquisition risk or seeking testing due to concern of exposure. Thus, population-level estimates are needed to estimate the overall burden of HIV among migrants and refugees in Colombia and neighboring countries to inform local and national treatment distribution and prevention plans.

RESEARCH OBJECTIVES

The primary objective of this study was to estimate HIV prevalence among recently arrived adult Venezuelans in urban host settings of Colombia. The study was designed to identify correlates of infection as well as provide qualitative estimates of engagement along the HIV care continuum among Venezuelan PLHIV. Given lack of information on the overall livelihood, health, displacement experiences, and experiences of discrimination and violence, additional information was collected in these domains noting their relationship to HIV as social and structural determinants of health as well as to inform local health and humanitarian services. Complex migration pathways across Latin America as well as the intense global migration and displacement trends currently witnessed suggest that study results may have regional generalizability and methods may inform global research and surveillance for migrants and refugees, respectively.

Methods

Methods

This study, known locally as *Bienestar de Venezolanos quienes son Inmigrantes y Refugiados* (*Proyecto BIENVENIR*) ("Wellbeing of Venezuelans who are Immigrants and Refugees") was a cross-sectional sociobehavioral survey to capture experiences regarding displacement history, migration history, healthcare access, health history, mental health, experiences of discrimination and violence, humanitarian service access, and engagement with the HIV care continuum among PLHIV.³⁸ The study also used a hybrid sampling and case finding approach, coupled with medicolegal services to link individuals with HIV diagnosis to HIV treatment and care, regardless of migration status. A qualitative, formative research phase was conducted to assess barriers to HIV care and health services in Colombia and to inform the quantitative research methods.

SETTING AND SAMPLE

Data collection activities were conducted in two sites, encompassing the neighboring cities of 1) Bogotá and Soacha Cundinamarca Department, and 2) Barranquilla and Soledad, Atlántico Department (Figure 4). Locations were selected for the distribution and heterogeneous profiles of Venezuelan migrants and refugees, accessibility to humanitarian and health programs, plans for treatment distribution, and lower presence of *pendulares*, Venezuelans who live in Venezuela but who cross to Colombia regularly to access services, and *caminantes*, Venezuelans who are transiting through Colombia to another country. We made an intentional decision not to sample in Cúcuta, given the existing extensive provision of services and treatment for migrants living with HIV and high presences of *pendulares*, which would bias estimates for migrants and refugees who continue to reside long-term in Colombia.

In the design of the study and analysis of data, the selected cities were coupled to create 'sites' for two reasons. First, the close proximity between coupled cities (e.g. Bogotá and Soacha) leads to regular movement of residents across the cities for a variety of reasons. This facilitated convenience for participants by allowing them to participate in a city where they may work or access services (e.g. Bogotá) even when residing in the other city (e.g. Soacha). Second, the sample size was powered to detect HIV prevalence within a specific margin of error within each site. Sample and population estimates reported throughout the manuscript are stratified by site, however, we include sample estimates stratified by city of residence in the Appendix of this report.

CREDIT: ADOBE STOCK

Figure 4 Population distribution of Venezuelan migrants and refugees in Colombia as of 2021

(Source: Department of Migration)

All adult Venezuelan nationals who recently migrated to Colombia were eligible to participate. To ensure recruitment depth in the network of Venezuelans, only one member in an immediate family was eligible to participate. Inclusion criteria were as follows: Venezuelan national based on self-report (proof/documentation of nationality was not requested); born in Venezuela based on self-report; aged 18 and over; migrated to Colombia as of 2015 or later; currently residing (i.e., spends most of their nights) in a study city; and brings a valid study coupon to enrollment (except seeds). Participants with any of the following characteristics were excluded from participation: previously participated; had an immediate family member in the same household who participated; resided outside of Colombia; reported being in transit through Colombia (i.e., reports an immediate destination outside of Colombia); and/or lacked capacity to consent. Dual Colombian citizenship or other dual citizenship did not impact eligibility of those meeting criterion of Venezuelan nationality.

RECRUITMENT

45

Respondent-driven sampling (RDS), a chain referral sampling method that employs limited referrals within peer networks to achieve target sample sizes, was used to accrue the study sample.³⁹ Recruitment started with 20 "seeds" (~10 per territory), well-networked individuals who were selected from the target population. Seeds were purposively selected based on being well-respected and influential among peers, socially networked (knew at least 10 Venezuelans outside of their household), and were diverse in characteristics (e.g., age, gender, geographic residence within each city). Seeds participated in all study activities and were asked to invite up to four adult Venezuelan peers (recruits) to participate in study activities, which was the first sampling wave. Eligible and participating recruits were then asked to refer up to four more peer Venezuelans living in the study cities. Participants could refer peers who lived in any of the four study cities, regardless of whether it was different from the city in which the referring peer resided. At the end of each study visit, participants underwent a brief training on how to distribute coupons and refer peers to the study. Participants had the option to use paper and/or e-coupons via SMS or WhatsApp to refer peers. Integration of the data management system allowed for automated reminders to be sent via SMS or WhatsApp, depending on preference, to participants to remind them to distribute coupons and of upcoming study visits.

Participants received \$30,000 Colombian pesos (approximately \$9 USD) compensation for completing study activities. Payment was in the form of a \$5,000 transport card and a \$25,000 market card. Additionally, participants received \$10,000 pesos (roughly \$3 USD) for recruitment of each eligible peer, up to four peers (maximum secondary incentive: \$40,000 pesos or roughly \$12 USD). This compensation was in the form of a transport card.

SURVEY MEASURES

Survey measures included individual, social, and structural domains, drawing upon previously developed measures, as applicable.^{19,39-53} Survey modules included the following domains and drew on previously developed and validated measures, where possible and relevant to the population: demographics; displacement experiences; food security;⁵⁴ health history including depression symptoms measured by the Patient Health Questionnaire for Depression and Anxiety (PHQ-4),^{23,49,50,54} hazardous alcohol use, measured by AUDIT-C,^{45,46} and drug use;⁵¹ COVID-19 symptoms and testing history; reproductive health; sexual behaviors;⁵¹ healthcare; HIV testing, prevention and care;^{41,42,51,52} experiences of violence victimization, based on the ASIST-GBV screening tool developed by the research team at Johns Hopkins University;⁴⁴ discrimination measured using the Everyday Discrimination Scale;¹⁹ use of humanitarian services; and social network size questions used for RDS weighting procedures.³⁹ Other health indicators beyond HIV prevention and care measures were included for the purposes of assessing overall health status, identifying other health concerns that may particularly affect those who are living with HIV (e.g., malnutrition), and/or identifying correlates of HIV infection.

BIOLOGIC TESTING

Biologic measures included rapid HIV and syphilis screening using Standard Diagnostics (SD) BIOLINE HIV/ Syphilis Duo with finger prick blood specimen.¹⁷ SD BIOLINE HIV/Syphilis Duo has a reported sensitivity of 99.8% and specificity of 100% for anti-HIV antibody detection and a reported sensitivity of 90% and specificity of 99.9% for anti-*Treponema pallidum* antibody detection.¹⁷ Rapid test results were available to participants within 20 minutes.

Participants with a reactive result on either or both tests were asked to provide an additional venous specimen for laboratory-based confirmatory testing. Preliminary positive rapid HIV test results were confirmed via Western Blot testing performed with MP Bio HIV BLOT 2.2, following national HIV testing guidelines.¹⁸ CD4 and viral load quantification were also performed. HIV infection reported here is based on laboratory confirmed results.

Confirmatory syphilis testing was performed using HUMAN Diagnostics Syphilis RPR Test with titer. Syphilis infection was defined as reactive treponemal test, RPR titer >1:8, and participant report of either no prior diagnosis or previously diagnosed and treated syphilis infection.

Rapid testing and biological specimen collection were conducted in accordance with Colombian national requirements. All staff who completed biological specimen collection were auxiliary nurse technicians with training in laboratory specimen collection, phlebotomy, rapid test administration, post-test counseling for HIV and syphilis, and specimen management and transport. HIV and syphilis confirmatory testing, as well as CD4 and viral load quantification were performed by laboratories at the Instituto de Diagnóstico Médico in Bogotá and Barranquilla.

MEDICOLEGAL SERVICES AND LINKAGE TO CARE

All participants identified with HIV (previously or newly diagnosed) and/or with syphilis infection were referred to Red Somos staff to complete a legal triage in which their legal status in Colombia was reviewed by the assigned lawyer who provided support for any needed registration and appropriate pathways to care were identified. Red Somos also offered care navigation to these participants.

SAMPLE SIZE

The study sample size was powered to estimate HIV prevalence in each study site. Assuming a 1% HIV prevalence among general population, based on reports from local providers that suggested a range of 0.5% prevalence to 1.5%, alpha 0.05, 0.005 margin of error, and design effect of two that has been suggested for RDS,⁵⁵⁻⁵⁷ we estimated that a sample size of 3,043 per site was needed to estimate population HIV prevalence in each site (combined cities). This sample size provides a sufficiently small sampling fraction required by most of the RDS estimators,⁵⁸ given that the Venezuelan migrant populations are estimated to exceed 115,000 persons in both sites. To accommodate any over-enrollment during RDS, our target sample size was 6,200 across two sites.

ANALYSES

Data management and RDS diagnostic techniques were performed using RDS-Analyst platform⁵⁹ and RDSAT throughout the course of the study to maximize data quality as well as ensure that RDS assumptions were met and bias was minimized in sampling and estimation procedures.⁶⁰ Techniques included: assessment of recruitment depth, bottlenecks, homophily, and convergence across select variables such as HIV, age, gender, migration status, and other variables that may affect recruitment.⁶⁰

Descriptive analyses were performed to estimate prevalence of key demographic and health characteristics of the population. All estimates were also stratified by site and, where relevant, by other characteristics such as gender or migration status. All descriptive analyses included unweighted sample and RDS-weighted population-based estimates for the general adult Venezuelan population and were calculated separately for each study site or other characteristic of interest (e.g., gender, migration status).¹⁶ RDS-weighted analysis was performed using Stata Statistical software and the RDS-II (Volz-Heckathorn) estimator.⁶¹ Population estimates were calculated by incorporating RDS survey weights, based on self-reported network size, to calculate population prevalence and bootstrapping procedures to calculate associated 95% confidence intervals. For overall estimates (i.e., aggregated across sites), we incorporated complex survey design to account for clustering within sites. We conducted a sensitivity analysis by estimating overall population prevalence using both RDS-II weights and additional weighting to account for the proportion of refugees and in each site estimates; differences were negible with this additional weighting by population size, thus we utilized only RDS-II weights for aggregated estimates. Given interest in city-specific estimates, we calculated sample proportions for all study findings, which are reported in the Appendix. We did not calculate population estimates with RDS-weighting given that the study was not powered to provide estimates at the city-level. Both sample and population-based estimates are provided throughout the report, with 95% confidence intervals (95%CI) provided for population estimates. We calculated sample estimates only for variables in which denominators were too small due to skip patterns, subgroup analysis, or a result of many categorical options.

Our primary analysis focused on estimation of laboratory-confirmed HIV prevalence among the general population of Venezuelans residing in each of the two sampling areas (i.e., powered to produce HIV prevalence estimates separately for each site). We further estimated HIV prevalence by age group, gender, risk group (men who have sex with men, transgender people, people who report transactional sex, and injecting drug use), and among the general or key population overall. Similar analyses were repeated to estimate the prevalence of laboratory-confirmed syphilis infection. Bivariate and multivariable logistic regression models were used to identify and estimate correlates and the magnitude of association with HIV infection.

Among participants living with HIV infection (previously diagnosed or undiagnosed), we conducted further descriptive analysis to estimate the proportion previously diagnosed, engaged in HIV care, currently on ARV treatment, and virally suppressed to construct HIV care continuum estimates of recently immigrated Venezuelans living with HIV in Colombia. Status of diagnosis was defined as: Diagnosed, based on self-report or HIV-1 RNA less than 1,000 copies/mL, or Undiagnosed, as no self-reported diagnosis and supported by viral load (HIV-1 RNA >1,000 copies/mL). Penalized logistic regression models were used to identify correlates of viral suppression (HIV RNA <1,000 copies/mL) among people living with HIV. Penalized multivariable logistic regression methods reduce the risk of bias associated with small samples.⁶²

RDS-weights were not incorporated into the analytic models given that such weighting is not recommended for multivariable regression analysis. Multivariable models incorporated complex survey design to account for clustering within site strata. Final models were evaluated for goodness-of-fit and collinearity.

ETHICS

Study activities were reviewed and approved by the Ethical Review Committee at the Universidad El Bosque in Bogotá, Colombia, and the Institutional Review Board at Johns Hopkins Bloomberg School of Public Health. The protocol was also reviewed in accordance with CDC human research protection procedures.

Results

Data collection launched on July 28th 2021 in Bogotá, July 31st 2021 in Soacha, August 10th 2021 in Barranquilla, and August 18th in Soledad. Participants were enrolled through February 2022, with final followup of participants with HIV and/or syphilis diagnosis completed by end of March 2022.

RDS sampling was initiated by 21 seeds (10 in Bogotá and Soacha and 11 in Barranquilla and Soledad). Seeds were launched in a phased manner to ensure that distancing could be maintained within study sites. Of those initial seeds, all but one successfully referred eligible and participating peers. This produced a median and maximum recruitment depth of 9 and 17 waves, respectively. Convergence was met for key variables of interest (gender, migration status, HIV, and syphilis). Figure 5 displays an enhanced view of a single RDS network from one study seed in Bogotá and Soacha. Appendix Figure 17 and 18 display full RDS network graphs for each site. Each node in the graph represents a seed or recruited participants. Lines within the graphs display referral connections between participants.

Figure 5 Example RDS network from single seed, Bogotá and Soacha

Note: The seed is represented by the large central node. City of residence is represented by color: green, Bogotá, and orange, Soacha. This seed had a recruitment depth of 14 waves and was the source of referrals for 1,459 recruited participants.

STUDY POPULATION

In total, 6,506 individuals were recruited through RDS, 6,221 of whom were eligible and consented to participate and compose the analytic sample. Participants were relatively evenly split between study sites, with 26% reporting Bogotá as their city of residence, 24% residing in Soacha, 28% residing in Barranquilla, and 23% residing in Soledad. Four participants resided in Soacha but participated in the Barranquilla or Soledad sites while visiting. Women represented 65% of the study population and were more likely to enroll than men (34%) and trans or nonbinary participants (0.8%). Higher enrollment of women than men was anecdotally explained by the restriction of enrollment to one family member per household and gender norms associated with expectations of work and participation in health services (and, by extension research) within a partnership. A slightly higher proportion of men participated in Bogotá and Soacha than Barranquilla and Soledad (p<0.05).

DEMOGRAPHICS

Table 3 presents demographic characteristics of Venezuelan migrants and refugees in each site and overall. Participants were a median age of 32 years (IQR: 26-41 years). Over half had completed secondary education while approximately 22% had no education or completed only primary school. Another 22.3% had completed higher than secondary education with slight differences across sites. Employment was limited: 41.2% reported informal or under-the-table employment, which was slightly higher among participants in Barranquilla and Soledad than in Bogotá and Soacha. Over 40% were unemployed at the time of the study. However, a higher proportion of migrants and refugees in Bogotá and Soacha also reported full-time, formal employment though this was 11% or lower across sites.

Income and food insecurity reflected employment status. The majority reported income less than minimum wage, which was more common in Barranquilla and Soledad. Less than 10% overall were food secure, as measured by the USDA Food Security scale.⁵⁴ Food security was more common in Bogotá and Soacha than Barranquilla and Soledad (9.9% vs. 4.3%, respectively). The remainder had low (26.5%) or very low food security (65.7%) overall.

Table 3 Demographic characteristics of Venezuelan migrants and refugees by site, continued

Notes: n: denominator for subgroup; N: total study population; 95%CI: 95% Confidence Interval; IQR: interquartile range; Sample difference at *p<0.05 or **p<0.10 on chi²tests; ref: reference group not displayed; grayed out cells represent variables in which cells were too small to reliably compute population estimates.

DEMOGRAPHICS BY MIGRATION STATUS

Overall, 29.3% of migrants and refugees reported regular migration status and 70.7% irregular migration status. Those with regular status were more likely to be men (38.9% vs. 31.8%) and less likely to be women (60.9% vs. 67.6%) compared to people with irregular status (Table 4). People with regular migration status were also more likely to have completed higher education (31.7% vs. 18.4%) and to have high literacy (88.7% vs. 82.0%), compared to people with irregular migration status. Those with regular migration status were more likely to have formal full-time employment (12.8% vs. 7.2%), while people with irregular migration status were more likely to be unemployed (43.9% vs. 37.0%). Differences in income by migration status reflected differences in employment status. Food security was also lower for migrants and refugees with irregular status compared to those with regular status (6.6% vs. 10.9%).

DISPLACEMENT HISTORY AND EXPERIENCES

Overall, 29.3% of migrants and refugees reported a regular migration status and 70.7% irregular migration status. Irregular migration status was slightly higher in Barranquilla and Soledad (Table 5). As described above, regular migration status refers to the possession of any unexpired document permitting stay in Colombia, the implications of which include access to formal employment and access to health insurance in Colombia. Thus, irregular status refers to the absence of such documents and complications to accessing healthcare and maintaining a livelihood. Individuals in the process of obtaining documents may report irregular status.

Over half of migrants and refugees arrived between 2018 and 2019 with over two-thirds arriving via informal border crossings. Migrants and refugees living in Barranquilla and Soledad were also more likely to report arriving through a *trocha* or informal border crossing compared to those living in Bogotá and Soacha (74.0% vs 54.3%) and likely explains, in part, the difference in migration status across these two sites. Forty percent of migrants and refugees traveled alone to Colombia with the remainder traveling with some combination of family, friends or other group. Overall, slightly more than half of refugees and migrants reported traveling with family members, with no difference across sites; however, those residing in Barranquilla and Soledad were more likely to have traveled with all immediate family members than those in Bogotá and Soacha (67.0% vs. 49.9%). This may be explained by the geographic distance between study site cities and Venezuela and the high cost of living in Bogotá.

Table 5 Displacement history and experiences among migrants and refugees, stratified by site, continued

Notes: n: denominator for subgroup; N: total study population; 95%CI: 95% Confidence Interval; IQR: interquartile range; Sample difference at *p<0.05 or **p<0.10 on chi²tests; ref: reference group not displayed; grayed out cells represent variables in which cells were too small to reliably compute population estimates.
Primary motivations for migration to Colombia were different by site (p<0.05), with more migrants and refugees in Barranquilla and Soledad reporting food insecurity, though this was by far the most common motive for migration across both sites (Figure 6).

DISPLACEMENT HISTORY AND EXPERIENCE BY MIGRATION STATUS

While more than half of migrants and refugees arrived between 2018 – 2019, migrants and refugees with a regular status tended to report arriving earlier, whereas an additional 30% of irregular migrants and refugees arrived in 2020 and 2021, compared to 13% of regular migrants and refugees who arrived at the same time (Table 6). Consistent with one's migration status, it was more common for regular migrants and refugees to cross at formal border crossings and irregular migrants and refugees to use informal passages.

Within the category of regular migration status, 6.5% had both Venezuelan and Colombian citizenship. Some migrants and refugees with irregular status had initiated the process of documentation; some of this can be attributed to participants who had begun the application process for an ETP, which had begun to accept applications in May of 2021 but did not begin distribution of documents until 2022.

The primary motivation for migration did not vary meaningfully by migration status, with food insecurity leading, followed by job insecurity, and followed by other reasons (Figure 7). Notably, migrants and refugees with irregular migrant status more commonly reported food insecurity as their primary motivation, compared to those with regular migration status (54.0 vs. 49.2%). Migrants and refugees with regular status more commonly reported a lack of access to medicine (4.9 vs. 2.8) and violence (3.0 vs 1.7), as primary motivations for migration.

Figure 7 Primary motivation for migration, stratified by migration status

Among those who reported health as a primary motivation for migration (n=212), the majority were seeking primary healthcare (Figure 8). There was no difference by site or migration status in stated health motivations.

Figure 8 Primary health motive for migration among those reporting health as primary factor

HEALTH HISTORY

Venezuelan refugees and migrants reported generally high levels of health, with over three quarters reporting "good, very good, or excellent" health (Table 7). Roughly half had a self-reported body mass index (BMI) of overweight or obese, with this proportion being slightly higher in Barranquilla and Soledad.

Mean scores for anxiety/depression were 3.3 (SD: 3.13) with 20.7% screening positive for probable moderate or severe anxiety and/or depression on the PHQ-4 scale. This was different across sites, with 29.1% of migrants and refugees in Barranquilla and Soledad reporting symptoms compared to 15.9% in Bogotá and Soacha. Similarly, 21.1% screened for hazardous or active alcohol use disorder. Two percent reported a lifetime history of injection drug use. Among those with a history of lifetime injecting drug use, however, only 13% had injected drugs within the last year.

Prevalence and differences in health indicators by migration status

General self-reported health was high and similar across migration status (Table 8). There were no differences by migration status in terms of BMI, self-reported symptoms indicative of moderate or severe anxiety and/or depression, or alcohol use.

Over 25% of migrants and refugees reported believing that they had a COVID-19 infection at some point based on symptoms and/or exposure. This was more commonly reported by those with regular migration status, compared to people with irregular migration status; however, there was no difference in diagnosis of COVID-19 by migration status. Almost half of the population reported having at least one vaccination for COVID-19, which was more commonly reported by migrants and refugees with a regular migration status than those with an irregular status (55.2% vs. 44.3%).

Table 8 Health characteristics of migrants and refugees with regular and irregular migration status, continued

Notes: n: denominator for subgroup; N: total study population; 95%CI: 95% Confidence Interval; IQR: interquartile range; Sample difference at *p<0.05 or **p<0.10 on chi2 tests; ref: reference group not displayed; grayed out cells represent variables in which cells were too small to reliably compute population estimates.

Among those with irregular migration status, migration status was the most common barrier to vaccination, while conflicts with work and inability to register for the vaccine were more frequently cited barriers to vaccination among regular migrants and refugees (Figure 9). Regular migrants and refugees were eligible for free vaccination at same time as Colombian nationals, while eligibility for irregular migrants and refugees occurred after October 2021. The high proportion of irregular migrants and refugees reporting no vaccine due to migration status is likely because of this policy as well as a lack of awareness when vaccines became available for those with irregular status.

Overall, 80% of migrants and refugees who were not vaccinated reported interest in vaccination with no difference by site or migration status. For participants reporting disinterest in vaccination (n=584), the two most common reasons were concerns about side effects (60.7%) and distrust of the vaccine (38.2%; Figure 10).

Figure 10 Reason for disinterest in COVID-19 vaccination among those unvaccinated and reporting no interest

No difference by site or migration status

PRENATAL CARE

Among sexually active women, over half reported currently using contraception, which was marginally higher in Bogotá and Soacha, compared to Barranquilla and Soledad. Over 28% reported pregnancy at some point since arriving in Colombia, with no difference by site. Receipt of prenatal care, however, was less common in Bogotá and Soacha, than in Barranquilla and Soledad, as were number of prenatal care visits (Table 9).

Table 9 Access to and use of reproductive health and prenatal care among women in study sites

Notes: n: denominator for subgroup; N: total study population; 95%CI: 95% Confidence Interval; IQR: interquartile range; Sample difference at *p<0.05 or **p<0.10 on chi² tests; ref: reference group not displayed; grayed out cells represent variables in which cells were too small to reliably compute population estimates.

Reproductive health and prenatal care were generally not different by migration status in terms of sexual activity, number of births, or contraceptive use (not displayed). Notably, however, among women who were pregnant while living in Colombia (n=1,156), 14.3% of women with irregular status and 8.7% of those with regular status were pregnant at the time of the study (not displayed). Current pregnancy was not different by year of arrival. Women with regular migration status also reported marginally more prenatal care visits during their last pregnancy in Colombia (Figure 11).

Figure 11 Number of prenatal visits during last pregnancy in Colombia by migration status

Among the 50% of women who reported current contraceptive use, vasectomy or tubal ligation were the most common, followed by implant (Figure 12). Use and method were different across sites, however, with implants being a more commonly reported method in Bogotá and Soacha, compared to Barranquilla and Soledad. In the latter site, use of oral contraceptives was almost as common as implant methods.

Figure 12 Contraceptive methods used by migrant women in study sites

Among women reporting no contraceptive use (n=1,933), almost 20% reported post-menopause as the reason for non-use. Other reasons included concerns about side effects, lack of awareness on how to access contraceptives, religion, and cost, and were different across sites (Figure 13).

Figure 13 Reasons for no contraceptive use among women not using contraceptives, by site

HIV & SYPHILIS INFECTION

Almost all Venezuelan refugees and migrants reported being sexually active, with a median number of 1 sexual partner in the past 12 months (Table 10). Three-percent reported ever being diagnosed with an STI in Venezuela or Colombia; of these, 81.3% had been treated.

SEXUAL BEHAVIORS AND BEHAVIORAL RISKS, STRATIFIED BY SITE

Among those who were sexually active, nearly a third of the population reported condom use at last sex, with more participants reporting condom use in Bogotá and Soacha than Barranquilla and Soledad (Table 10). Only 1.1% of migrants and refugees reported having a partner who was living with HIV; however, 36.9% in Bogotá and Soacha and 67.7% in Barranquilla and Soledad did not know their current or most recent sexual partner's HIV status.

Key populations represented a small fraction of participants overall (6.8%), including those who reported lifetime history of paying for sex (1.2%), providing sex for transactional purposes (1.2%), injecting drugs (1.9%, Table 7), and men who reported sexual partnerships with men (12.0% of men).

Table 10 Sexual behaviors and behavioral risks for HIV, stratified by study site

Notes: n: denominator for subgroup; N: total study population; 95%CI: 95% Confidence Interval; IQR: interquartile range; Sample difference at *p<0.05 or **p<0.10 on chi² tests; ref: reference group not displayed; grayed out cells represent variables in which cells were too small to reliably compute population estimates.

SEXUAL BEHAVIORS AND BEHAVIORAL RISKS BY GENDER

There was little meaningful difference in sexual activity and number of sexual partnerships across gender, though condom use at last sex was different (Table 11). Almost 60% of transgender and nonbinary participants reported condom use at last sex, whereas 38.6% of men and 27.4% of women reported use of a condom at last sex. Overall, 14.9% of men and 2.4% of women reported a behavior or identity that aligns with a key population. Sexual partnership with someone known to be living with HIV was more common among men than women (2.4 vs. 0.4, respectively). There was no difference in lifetime STI diagnosis by gender.

Table 11 Sexual behaviors and behavioral risks among migrants and refugees, stratified by gender

Notes: n: denominator for subgroup; N: total study population; 95%CI: 95% Confidence Interval; IQR: interquartile range; Sample difference at *p<0.05 or **p<0.10 on chi²tests; ref: reference group not displayed; grayed out cells represent variables in which cells were too small to reliably compute population estimates; Key population defined as individuals who identify as transgender or nonbinary who have sex with men, are men who have sex with men, report lifetime transactional sex, or report lifetime injecting drug use; grayed out cells represent variables in which cells were too small to reliably compute population estimates.

Figure 14 displays the gender of sexual partners. Almost 90% of men reported sexual partnerships with women, though over 10% reported partnerships with men and/or with transgender or nonbinary partners. Relationships reported by women were predominantly heterosexual, though 5% reported partnerships with women. Transgender and nonbinary participants reported more diverse genders in sexual partnerships.

Figure 14 Gender of sexual partners (select all)

SEXUAL BEHAVIORS AMONG VENEZUELANS WITH REGULAR AND IRREGULAR MIGRATION STATUS

Venezuelans with regular and irregular migration status were generally similar in terms of sexual behavior and behavioral risks for HIV and STI (Table 12). Specifically, there was no difference in terms of sexual activity, number of sex partners, or history of transactional sex or purchasing sex. Notably, however, condom use at last sex was marginally lower among those with irregular status compared to regular migration status (29.7% vs. 34.7%). People with irregular migration status were marginally more likely to report not knowing their sexual partner's HIV status (50.0% vs 43.9%) compared to those with regular migration status.

HISTORY OF HIV TESTING AND PREVENTION

Overall, a little over half of refugees and migrants had ever been tested for HIV, which was more common in Bogotá and Soacha (56.2%) compared to Barranquilla and Soledad (46.9%; Table 13). Among those who had ever been tested, the majority had been tested more than one year ago. Among those with a lifetime history of HIV testing, 59.0% had been tested for HIV in Colombia and 40.2% had been tested while in Venezuela. Most (98.1%) reported a negative HIV result at their last test. Awareness and use of PrEP and nPEP were low. Only 12 participants in Bogotá and Soacha and 5 in Barranquilla and Soledad reported nPEP use in Colombia. PrEP use in Colombia was reported by 9 participants in Bogotá and Soacha and 5 in Barranquilla and Soledad.

PREVALENCE OF HIV INFECTION

A total of 71 participants were identified with laboratory confirmed HIV infection; all were informed of their test results, underwent legal triage, and were linked to HIV care during the study. Laboratory confirmed HIV prevalence among migrants and refugees across the two sites was 0.9% (95%CI: 0.6-1.4) and ranged from 0.8% in Bogotá and Soacha (95%CI: 0.4-1.5) to 1.2% (95%CI: 0.7-2.0) in Barranquilla and Soledad (Table 14). Assuming stable HIV prevalence among migrants and refugees and a population size of 2,477,588 refugees and migrants in Colombia, based on September 2022 migration estimates that includes all migration statuses,² this would equate to 22,298 (95%CI: 14,865 - 34,686) migrants and refugees living with HIV in Colombia and requiring ongoing access to treatment.

HIV prevalence was also higher among men (1.6%) relative to women (0.6%). Population HIV prevalence was not calculated for transgender and non-binary identified participants due to the small number (n=47); however, the burden of HIV was high among this group with 8.5% (4/47) identified with HIV infection. HIV prevalence was estimated at 6% among key populations, inclusive of migrants and refugees who reported lifetime transactional sex, injecting drug use, trangender people who have sex with men, and men who have sex with men. Notably, all key populations with HIV were men who have sex with men or transgender/non-binary people, though several also reported other HIV acquisition risk behaviors such as injecting drug use or transactional sex. There was no difference in HIV status by migration status nor year of migration.

DIAGNOSED AND UNDIAGNOSED HIV INFECTION

Among 71 participants with laboratory confirmed HIV infection, 34 (48%) were believed to be previously diagnosed based on self-report of positive last HIV test or HIV-1 RNA <1,000 copies/mL. Among participants with undiagnosed HIV infection, irregular migration status was more commonly reported than regular (75.7% vs. 24.3%). Only 43.2% of those with undiagnosed HIV infection had ever been tested for HIV. Ninety percent of those with a past diagnosis had been last tested or diagnosed in Venezuela. Forty percent of those with a past diagnosis still had detectable viral loads based on the Colombian guidelines above 50 copies per mL (Table 15).

Table 15 Characteristics of participants with past and new HIV diagnoses

Notes: n: denominator for subgroup; N: total study population; Sample difference at *p<0.05 or **p<0.10 on chi² tests; ref: reference group not displayed; CD4 and viral load data are missing for one participant who had previously been diagnosed and declined further laboratory testing. Sample estimates are provided given small number of events.

CORRELATES OF HIV INFECTION

Multivariable regression models were used to identify correlates of HIV infection among migrants and refugees overall (Table 16), as well as within each gender category (Table 17). Women were 50% less likely to have HIV infection (aOR 0.5; 95%CI: 0.3-0.8), relative to men, while transgender or nonbinary identified participants had four times the odds of infection (aOR:4.1; 95%CI: 1.5-11.2). Likewise, reporting a behavior or identity of a key population at risk for HIV was associated with almost four times the odds of infection, compared to those identified as the general population (aOR: 3.8; 95%CI: 2.1-6.6). Migrants and refugees who reported experiences of sexual exploitation for resources while in Colombia (aOR: 3.1; 95%CI: 1.1-9.1) or who reported a lifetime STI diagnosis (aOR: 11.3; 95%CI: 6.4-20.1) were more likely to have laboratory confirmed HIV infection. Finally, partnership with someone known to be living with HIV was associated with a 15-fold increase in HIV infection (aOR: 15.3; 95%CI: 6.6-35.6). Current or former marriage, food insecurity, transactional sex, and condom use at last sex were associated with HIV infection in bivariate analyses but were no longer associated with infection in multivariable models. Migration status, history of injecting drug use, and number of sexual partners were not associated with infection status.

| | OR | 95%CI | p-value | aOR | 95%CI | p-value | | | | | | |
|---|------|-------------|---------|------|------------|---------|--|--|--|--|--|--|
| Gender (Reference: man) | | | | | | | | | | | | |

| | | | | | | | | | | | | |

Table 16 Correlates of HIV infection among full study population

Note: OR: unadjusted odds ratio; aOR: adjusted odds ratio calculated via a multivariable regression model; model is adjusted for age and incorporates complex survey design to account for clustering within site strata; final model is fit based on goodness of fit statistics and tested for collinearity; final model sample size is 5,972.

Correlates of HIV infection were unique within each gender category (Table 17). Among men, infection was independently associated with same sex relationships (aOR: 7.5; 95%CI: 3.4-16.9), lifetime STI diagnosis (aOR: 10.6; 95%CI: 4.5-24.8), and sexual relationship with someone known to be living with HIV (aOR: 9.7; 95%CI: 2.7-35.2). Infection was marginally associated with sexual exploitation in Colombia (aOR: 4.2; 95%CI: 1.0-17.7).

Among women, infection was associated with lifetime STI diagnosis (aOR: 10.0; 95%CI: 4.3-22.9) and a relationship with someone known to be living with HIV (aOR: 31.4; 95%CI: 10.4-94.8). Multivariable regression was not modeled for transgender or nonbinary identified participants given the small number of participants. In bivariate analysis, laboratory confirmed syphilis infection was associated with laboratory confirmed HIV infection (aOR: 7.6; 95%CI: 0.8-73.6).

Table 17 Correlates of HIV infection in each gender category

Note: OR: odds ratio; aOR: adjusted odds ratio calculated via a multivariable regression model; multivariable models were not fit for transgender or nonbinary identified participants based on the small number identifying as such; all models are adjusted for age and incorporate complex survey design to account for clustering within site strata; final models are fit based on goodness of fit statistics and tested for collinearity; final model size are: 2,008 among men, n=3,921 among women, and n=47 among transgender or nonbinary participants; grayed out cells represent variables in which cells were too small to reliably compute population estimates.

ACCESS TO HIV TREATMENT AND CARE FOR PEOPLE LIVING WITH HIV

Figure 15 displays the HIV care continuum for participants living with HIV. The most significant drop in the HIV care continuum was observed with diagnosis, wherein only 47.9% of people living with HIV had been aware of their infection. Lack of awareness of one's status then impacts all subsequent stages of the continuum. Sevent-nine percent of those ever diagnosed were currently on treatment and 92.6% of those on treatment were virally suppressed (HIV-1 RNA <1,000 copies/mL). Overall, however, this represents 35.2% of people living with HIV who were virally suppressed. Twenty-nine percent of people living with HIV had an undetectable viral load (HIV-1 RNA <50 copies/mL).

Figure 15 HIV care continuum among participants with laboratory-confirmed HIV infection (n=71)

Among 26 participants who reported ever receiving ARV treatment, 35% (9/26) and 73% (19/26) had received ARVs in Venezuela and Colombia, respectively. Among 19 participants who received ARVs in Colombia, 68% (13/19) had received through the national insurance, 26% (5/19) through humanitarian permits, and 21% (4/19) from community-based organizations (not displayed). Several also reported receiving treatment from other sources including private providers and informal redistribution of medications. Information about sources of treatment should be viewed with caution due to small numbers who report lifetime ARV use.

CORRELATES OF VIRAL SUPPRESSION

Penalized multivariable logistic regression modeling was used to identify correlates of viral suppression among participants living with HIV (n=71), in which viral suppression was defined as HIV-1 RNA <1,000 copies/ mL (Table 18). Penalized multivariable logistic regression methods reduce the risk of bias associated with small samples. In the adjusted model, having an irregular migration status compared to a regular status was associated with 70% reduced odds of viral suppression (aOR: 0.3; 95%CI: 0.1-0.9), while having a last HIV test or diagnosis in Colombia, compared to Venezuela, was associated with 90% reduced odds of viral suppression (aOR: 0.1; 95%CI: 0.0-0.5). Likewise, those who were never tested for HIV had 80% reduced odds of viral suppression, compared to those last tested in Venezuela. Reporting behaviors or identity associated with a key population and use of humanitarian services in Colombia were associated with viral suppression at the bivariate level but were no longer associated in the multivariable models. Gender, time since migration, site, age, income, food security, and BMI were not associated with viral suppression in bivariate or multivariable models. In sensitivity analysis, using undetectable viral load (HIV RNA <50 copies/mL) as the outcome, there was no meaningful difference in identified correlates (results not displayed).

Table 18 Correlates of viral suppression among migrants and refugees living with HIV

Note: OR: odds ratio; aOR: adjusted odds ratio calculated via a penalized multivariable logistic regression model for small denominators; final models are fit based on goodness of fit statistics and tested for collinearity; grayed out cells represent variables in which cells were too small to reliably compute population estimates.

PREVALENCE OF SYPHILIS INFECTION

Prevalence of laboratory-confirmed syphilis infection migrants and refugees was 5.0% (95%CI: 4.1-6.0; Table 19) with no difference across sites, age, or migration status. Notably, 9.2% of women who were pregnant at the time of the study had syphilis infection, though the estimates for those who were ever pregnant while living in Colombia were similar to those for all women (4.1%, 95%CI: 3.2-5.4, not included on table). Among the sample of transgender and non-binary identified participants, 14.9% (unweighted) were identified with syphilis infection. Syphilis prevalence was estimated at 15.2% among key populations overall and as high as 18.2% among men who have sex with men. Almost one-quarter (23.9%) of participants with a laboratory-confirmed HIV infection had a syphilis co-infection.

EXPERIENCES OF DISCRIMINATION AND VIOLENCE VICTIMIZATION

Participants were asked a series of questions about experiences of discrimination while in Colombia, based on the 5-item Everyday Discrimination (Short) scale.¹⁹ Almost half (46.7%) of migrants and refugees reported experiencing at least one form of discrimination a few times per year or more frequently. Of these, 90.0% believed stigma and discrimination were targeted on the basis of their migration status (Table 20).

Participants were also asked a series of questions about experiences of psychological, physical, and sexual violence victimization and sexual exploitation while living in Colombia. Participants who reported any experience of violence were asked additional questions about who perpetrated violence and if violence occurred in the last 12 months. Overall, 12.2% of participants reported experiencing violence while living in Colombia, which most commonly included psychological abuse (8.3%), physical violence (7.0%), sexual exploitation (2.0%) and sexual violence (1.4%). Estimates of violence while living in Colombia *should not* be compared to national estimates of lifetime violence given that enrollment was restricted to Venezuelans who arrived since 2015; thus, the estimates presented here represent experiences within a maximum of six years. Overall, 6.2% of migrants and refugees reported violence victimization in the last 12 months (Table 20).

PREVALENCE AND DIFFERENCES IN DISCRIMINATION AND VIOLENCE VICTIMIZATION ACROSS SITES

Experiences of discrimination was more commonly reported among migrants and refugees in Bogotá and Soacha than Barranquilla and Soledad (50.7% vs 42.3%, p<0.05; Table 20). Figures 16 and 17 display the scale responses to experiences of discrimination within each site.

Figure 16 Frequency of stigma and discrimination reported by migrants and refugees in Bogotá and Soacha

Figure 17 Frequency of stigma and discrimination reported by migrants and refugees in Barranquilla and Soledad

Overall, 12% of participants reported experiencing violence while living in Colombia. Any violence victimization was marginally higher in Bogotá and Soacha than Barranquilla and Soledad (13.6 vs. 9.8% reporting any form of violence victimization while in Colombia, respectively; Table 20). Notably, individuals reported to perpetrate violence were different across sites. In Bogotá and Soacha, strangers, employers, police, armed groups, were more likely to be identified as perpetrators across all forms of violence than reported in Barranquilla and Soledad. Conversely, intimate partners and family members were more commonly reported to perpetrate violence in Barranquilla and Soledad than reported in Bogotá and Soacha.

PREVALENCE AND DIFFERENCES IN DISCRIMINATION AND VIOLENCE VICTIMIZATION ACROSS GENDER

Experiences of discrimination and violence victimization while living in Colombia appeared to be slightly higher among men than women, though with overlapping confidence intervals (Table 21). Overall, 14.9% of men and 10.8% of women reported at least one form of violence victimization while residing in Colombia. Generally, women more commonly reported that intimate partners had perpetrated violence, while men more commonly reported perpetration by police, armed groups, and strangers. Intimate partner and intrafamilial violence may be lower than anticipated either due directly to lower experiences of violence due to family separation during migration or due to under-reporting of these experiences.

More than half of transgender and nonbinary participants reported higher levels of discrimination (sample estimate: 57.5%) while 12.8% reported experiencing any form of violence while living in Colombia. Experiences of sexual violence and sexual exploitation were exceptionally high among transgender and nonbinary identified migrants and refugees. These estimates may be limited by the small number of migrants and refugees identifying as transgender or nonbinary, though they mirror global and national reports of experiences of discrimination and violence experienced by transgender people.⁶³

PREVALENCE AND DIFFERENCES IN DISCRIMINATION AND VIOLENCE VICTIMIZATION ACROSS MIGRATION STATUS

Experiences of discrimination and violence were generally similar across migration status (Table 22). Refugees and migrants with regular migration status were slightly more likely to report experiences of discrimination (48.1% vs. 46.2%) and any violence victimization (13.1% vs 10.9%) while living in Colombia, compared to those with irregular migration status. Differences in any violence victimization were largely driven by slight differences in psychological abuse, physical violence and marginally by sexual violence. Strangers and partners remained the most commonly reported group to perpetrate violence, with no difference by migration status. Employers were more commonly reported by those with regular migration status were more likely to report that NGO workers had perpetrated psychological abuse and physical violence, compared to those with regular migration status.

HARDSHIPS AND UPTAKE OF HUMANITARIAN SERVICES

Overall, the majority of migrants and refugees reported experiencing some hardship while living in Colombia (Table 23). These most commonly included financial hardship (50.2%), food insecurity (19.7%), and housing (16.4%). Despite these challenges, only 17.3% of migrants and refugees reported utilizing humanitarian services. Among those who utilized services, these services often included food assistance (59.5%), support for accessing national health services (32.6%), healthcare (27.7%), and legal assistance (17.9%).

PREVALENCE AND DIFFERENCES IN UPTAKE OF HUMANITARIAN SERVICES BY SITE

Financial hardship was the most common form of hardship across sites, though it was slightly higher in Barranquilla and Soledad, while food insecurity was marginally more common in Bogotá and Soacha (Table 23). There was no difference in overall utilization of humanitarian services across sites, though the type and provider of services differed across locations. This likely reflects the location in which agencies are based and type of services associated with those agencies.

PREVALENCE AND DIFFERENCES IN UPTAKE OF HUMANITARIAN SERVICES BY MIGRATION STATUS

When asked about the greatest hardship, financial hardship remained the most commonly reported hardship across migration status, though it was slightly higher among those with regular migration status compared to irregular status (54.5% vs. 48.4%; Table 24). Migrants and refugees with irregular status were marginally more likely to experience hardships related to housing (17.4% vs 14.0%) and education (4.3 vs 1.7%) than migrants and refugees with regular migration status. No differences were observed for hardships related to food security, the second most commonly reported hardship, or security concerns.

Migrants and refugees with regular status were more likely to have reported the use of humanitarian services compared to those with irregular status (21.9% vs. 15.4%), though still fewer than one in five reported utilization of such services. Compared to irregular migrants and refugees, regular migrants and refugees were more likely to have used legal or registration assistance, assistance with accessing national health services, and psychosocial support, as well as services provided by UNHCR, which collectively may explain achievement of regular migration status.

Conclusion and Recommendations

Conclusion and Recommendations

This study successfully enrolled over 6,200 migrants and refugees residing in two urban settings of Colombia within eight months. The successful implementation is attributed to the community trust in the organization implementing field research, support for legal process to ensure linkage and sustained access to care for people diagnosed with HIV or syphilis, regardless of migration status, and the use of RDS-methodology that leverages social networks within populations that lack sampling frames. The RDS methodology provides an added benefit of producing unbiased estimates that approximate population estimates and overcome limitations associated with other convenience sampling approaches and HIV estimates generated through testing programs.

Age distribution and timing of arrival reported here generally reflect what is reported by migration agencies for Venezuelans living in Colombia.²⁰ Our findings, however, also highlight social and structural vulnerabilities, including low educational attainment, low levels of formal employment and, thus, material hardships including low income, food insecurity, and housing instability. These likely reflect the long-term impacts of the financial crisis in Venezuela, but also immediate challenges facing Venezuelans in Colombia. For example, food insecurity was the most common reason for migration from Venezuela, however, food insecurity was the second most common reported hardship in Colombia, after financial difficulties.

Experiences of discrimination and violence while residing in Colombia, reported by 47% and 12% of the population respectively, suggest the existence of social tensions between the host and migrant community as well as the stress of displacement within families and intimate relationships. There are no estimates of discrimination and violence for Venezuelan refugees or migrants nor for adults of all genders in Colombia for comparison. However, given general vulnerabilities of migrants and refugees, our estimates may be lower than anticipated and may be attributed to the country's reputation for welcoming Venezuelans. Our formative, qualitative research found evidence of more recent tensions during the COVID-19 pandemic and associated economic impacts, which may suggest a shift in attitudes towards Venezuelans and may translate to increased discrimination and/or violence in the near future. Ten percent of women refugees and migrants reported experience of violence while living in Colombia; though not directly comparable, this is similar to national estimates of life-time and past 12 month intimate partner violence reported for ever-partnered women in Venezuela (19% and 8%, respectively) and lower than reported in Colombia in 2018 (20% and 12%, respectively).²¹ It is possible that separation of partners and families during migration may result lower reports of intimate and intrafamilial violence. These forms of violence may also be under-reported due to stigma or misclassification of less severe forms of violence.

In terms of health indicators, self-reported health status among migrants and refugees was generally high and may reflect the hypothesis known as the 'healthy migrant effect', in which migrants are often healthier than host communities across a number of health indicators.²² Other studies have supported that hypothesis, though they have also shown that health of migrants tends to decline with length of stay, typically as a result of low living and working conditions.²² Indeed, mental and behavioral health indicators for Venezuelan migrants and refugees in this study were remarkable. Mean mental health scores on the PHO-4 among migrants and refugees were considerable higher in this study than previously reported for the Colombian population in 2014 (3.3 vs. 1.3),²³ with one-fifth of migrants and refugees in this study reporting symptoms of anxiety or depression, as well as alcohol use disorder. Uptake of COVID-19 testing and vaccination was low, particularly among irregular migrants and refugees, and likely reflects differences in timing of vaccine eligibility across these subpopulations but also (lack of) awareness of available services in Colombia. Finally, 5% of migrants and refugees had laboratory-confirmed syphilis infection. These estimates are far higher than 0.7% estimated prevalence among Colombian adults in 2016,²⁴ though cases of syphilis have increased in the country and regionally since that time.²⁵ The high prevalence of syphilis infection raises concerns for risks associated with untreated syphilis, congenital syphilis among other risks for neonates, and onward transmission of infection.

The prevalence of HIV was also noteworthy. Population HIV estimates bordered 1% (overall population prevalence: 0.9%; 95%CI: 0.6-1.4) and were higher in Barranquilla and Soledad (1.2%) than in Bogotá and Soacha (0.8%). HIV prevalence was 6% among key populations. Population prevalence of HIV was higher than

reported for Venezuela (0.5%)²⁶ and observed in Colombia (0.5%).²⁷ Low engagement across the HIV care continuum, beginning with low HIV diagnosis and ultimately low levels of viral suppression, signals a need to increase uptake of HIV testing and support long-term and consistent engagement in care for improved individual health outcomes as well as to prevent onward transmission of infection. The estimates reported here for Venezuelan migrants and refugees residing in Colombia are close to those long defined by UNAIDS and WHO as a generalized epidemic²⁸ and highlight the importance of improving access to and uptake of HIV prevention and care among Venezuelan migrants and refugees are not key populations and services for migrants and refugees should not be provided through key populations programs but incorporated through programs for the host population and via humanitarian programming.²⁹ Given that HIV burden was highest among key populations, programs serving key populations should continue to be supported, if not enhanced, to provide services to key populations regardless of nationality or migration status.

This study also identified notable disparities across migration status and geographic residence. Health history and services use suggested lower availability or access in Barranquilla and Soledad. Financial hardship was the most commonly reported hardship across both sites but was more common in Barranquilla and Soledad, while food and housing more commonly reported hardship in Bogotá and Soacha. Differences speak broadly to the higher cost of living associated with Bogotá but also lower availability of services available in Barranquilla and Soledad, compared to Bogotá and Soacha. The differences across sites may also reflect differences in migration status among Venezuelans living in the two sites.

Venezuelan refugees and migrants with irregular migration status faced a number of social, structural and health vulnerabilities, compared to those with a regular migration status. Irregular migration status was associated with lower educational attainment, employment, income, food security, BMI, and higher levels of probable depression and anxiety, which collectively may reflect legal access to employment and other basic services. Low levels of condom use, awareness of partner status, diagnosed HIV infection, and viral suppression among people with irregular migration status reflect lack of access to insurance coverage for health and HIV services that are tied to legal migration status. Prenatal care is available regardless of migration status, but we observed a lower number of prenatal visits among women with irregular status, which likely reflects other barriers that may be associated with education or discrimination. People with irregular migration status were also less likely to access humanitarian services. Despite these differences, health, social, and structural indicators were poor among Venezuelan refugees and migrants, overall. These findings highlight a need for improved access to services in addition to support migrants and refugees to understanding rights and services, particularly for those with lower literacy and education. For those with irregular status, methods to facilitate registration for the Temporary Protection Permit would improve access to health and other social services for an estimated 800,000 Venezuelans in Colombia.⁷

Study findings suggest multiple opportunities for intervention. We recommend the following strategies for public health programming and policy to support improved health and well-being of Venezuelans living in Colombia.

RECOMMENDATIONS:

These findings highlight several opportunities to support the health, well-being, and livelihood of the Venezuelan population residing in Colombia. As efforts are underway to provide inclusive health services for the 2.5 million Venezuelan refugees and migrants in the country, it is important to ensure that laws, policies and programs respect, protect, and fulfil the rights of all refugees and migrants, including protection from discrimination based on nationality, migration status, gender, and HIV status. Further, policies and program should be designed, implemented, monitored, and evaluated with the participation of refugees and migrants.²⁹

Policy and programming for HIV, sexual, and reproductive health may consider:

- 1. Encourage the national government and donor agencies to provide the same access to HIV care for refugees and migrants, regardless of migration status, as nationals receive.
- 2. Consider establishing inter-institutional alliances (governmental, territorial entities, humanitarian organizations, community-based organizations, and organizations servicing refugees and migrants) that facilitate networks for community support involving existing organizations as well as the host communities, for the diffusion of information regarding preventative health, sexual and reproductive health, and public health surveillance.
- 3. Promote strategies for the timely diagnosis of HIV, syphilis, and other STIs among refugees and migrants in the Territorial Health Plans (*PTS, Planes Territoriales de Salud*)⁶⁴ and Collective Interventions Plan (*PIC, Plan de Intervenciones Colectivas*) in Colombia's territories with highest populational migrant density, ensuring that uninsured refugees and migrants are classified as a vulnerable population to be included in these plans. These strategies may include actions to integrate Venezuelan migrants and refugees, regardless of migration status, in health services along with the host community and involve community-based organizations who have experiences working with these populations.
- 4. Implement a communication campaign and training, led by the Ministry of Health and Social Protection and territorial entities, to reduce the double stigma and discrimination faced by refugees and migrants in healthcare contexts due to their nationality and HIV status. These actions should include a specific focus on this population through an investment in human resources in healthcare and communication campaigns to the general population to improve the adoption of these changes and reduce barriers to accessing services.
- 5. Execute public financing programs in coordination with cooperating organizations to invest in and develop promotional health and STI prevention programs with an inclusive and multicultural focus. This should include the combination prevention package for migrants and refugees, including PrEP, PEP, ART, rapid HIV and syphilis tests, partner services, coupled with substance use and mental health services, alongside other evidence-based approaches. The development of these programs should benefit from the expertise of local organizations with backgrounds working with these populations and interorganizational cooperation.
- 6. Consider revising the Collective Interventions Plan (*PIC*, *Plan de Intervenciones Colectivas*) to guarantee diagnosis, confirmation, and immediate treatment for syphilis in persons with positive screening results via insurance provided by the national health system. Until insurance coverage is possible, free access to syphilis testing and immediate treatment should be provided to prevent transmission. Such a change and subsequent reduction of barriers to treatment would reduce the impact of syphilis on reproductive and sexual health, among both refugees and migrants and as well as members of the host community who lack insurance.
- 7. Support increased financing of community programs provided by civil society that target the provision of medical attention for refugees and migrants living with HIV, including psychosocial support, humanitarian aid, and medical attention as well as technical capacity building for the development of these programs as they are a direct channel to the migrant population.
- 8. Provide support for organizations that provide prevention and self-care in the realm of sexual and reproductive health, including the prevention of HIV and other STIs. Organizations must provides a multicultural focus on refugee and migrant populations with consideration to intersectional vulnerabilities experiences by migrant/refugee gay and bisexual men, transgender people, and people engaged in transactional sex.
- 9. Guarantee access to preventative methods in sexual and reproductive health, such as education, prevention activities, and free contraception and condoms to reduce the transmission of HIV, other STIs and/or unplanned pregnancies. These actions can be developed through collaboration across the Collective Interventions Plan (*PIC, Plan de Intervenciones Colectivas*) led by territorial entities, insurance health companies, humanitarian organizations, and civil society.
- 10. Encourage support for research related to migration patterns and HIV to establish an evidence base, monitor trends, and inform policy and programmatic decisions. This may include population-based and cohort designs to evaluate HIV, syphilis, other STIs, other infectious diseases, such as COVID-19, as well as access to healthcare, treatment, and adherence among refugees and migrants.
- 11. Generate appropriate mechanisms so that international organizations providing HIV care services to migrants and refugees living with HIV can report to established information systems such as Sistema Nacional de Vigilancia en Salud Pública (SIVIGILA) and the High Cost Account on a regular basis.
- 12. Provide appropriate governmental or international cooperation resources to undertake HIV prevalence studies that are focused on the health of the Venezuelan migrant population, expanding coverage of studies to other cities, and/or repeating them on a regular basis. These should be designed and implemented in such a way that there is comparability over time and results may serve as input for the calculation of national prevalence estimates that are reported to the Global AIDS Monitoring (GAM) and that are carried out with the support of UNAIDS, using the Spectrum tool.²⁷
- 13. Incentivize organizations to create policies, strategies, and plans for HIV care for other target populations, thereby reducing stigma associated with HIV among migrants and refugees.

Policy and programming for general health concerns, inclusive of mental and behavioral health, may consider the following:

- 1. Disseminate information about routes and mechanisms to access health care for refugees and migrants to facilitate timely medical attention and eliminate situations of denial or discrimination. This should include improved knowledge of the operation of the state, migrants' rights, and the availability of existing services. This can be achieved through organizational networks, which process recently arrived migrants, who are still in the course of resettlement, as well as those who already reside in Colombia, to assist migrants with navigation of insurance and access to health services.
- 2. Include mental health components and clear referral pathways to mental health services in health programs offered to refugees and migrants.

Policy and programming for migration and humanitarian services may consider the following:

- 1. Facilitate registration for the Temporary Protection Permit (ETP) by Venezuelans with irregular migration status, thereby conferring legal protection and access to health and other social services.⁷
- 2. Support communication campaigns organized by the Ministry of Health and Social Protection and territorial entities directed at refugees and migrants which cement the right to insurance, access to universal, equal, and timely healthcare free of stigma and discrimination. These may include informational materials displayed and/or distributed at border crossings, as well as more detailed materials available at health centers, community centers, and other humanitarian arenas. These materials should clearly delineate the rights afforded to migrants and refugees, as well as contact information for organizations which can provide support. Accommodations should be made to aid refugees and migrants with low literacy or education in understanding these rights.

- Support local and national humanitarian programs to provide HIV care, including community
 organizations, so they may provide services to refugees and migrants with irregular migration status
 until they can access care through the national health system.
 Capacitate governmental organizations, humanitarian organizations, and civil society to meet the
 needs of refugees and migrants accessing services. Capacity building can leverage the expertise of
 interorganizational alliances, develop processes for training with a focus on cultural sensitivity and
 gender-specific needs to guarantee the human rights of refugees and migrants.
- 4. Involve host communities in community services for refugees and migrants, including activities focused on integration through art in which individuals may reflect on themes such as migration. Risks associated with migration may be reduced through the promotion of clear and accurate information regarding human rights and available services for migrants and refugees.
- 5. Support collaboration of local and national governments and human rights organizations to assure compliance with laws, policies, and programs that protect and serve migrants and refugees, as well as persons living with HIV.
- 6. Create opportunities for migrants and refugees to join the labor force, including validation of the education titles, which allow migrants and refugees to enter the work force based on prior training, and subsequently provide access to health insurance.
- 7. Integrate social protection measures into the migration response with a focus on food insecurity and labor rights and their role as determinants of health. These measures should include the provision of guaranteed basic food supply.
- 8. Ensure programs maintain ongoing communication with Venezuelans using their services to receive feedback regarding the humanitarian supports; monitor updates regarding migration, educational, or labor status; and establish ongoing psychosocial support.
